The Dunmore Pear.—The season for planting being at hand, I wish to recommend the Dunmore Pear to intending planters as highly deserving of notice, both for its excellence, and also on account of its coming into use between the seasons of Williams' Bon Chrétien and Marie Louise. The tree is very hardy, a vigorous grower, and bears most abundantly as a standard. It is, moreover, well adapted for cold or late situations. A standard tree here very rarely fails having a good crop. It is one of the best and most melting Pears in its season, and is deserving a place in a collection of choice Pears.—M. SAUL, in *Florist*.

Orchards on Grass.—Hundreds of acres of Apple orchards may be seen near Maidstone, some on Grass and some with bush fruits between the trees, Gooseberries, Currants, and Nuts being the general undercrop. During this season, however, many fine plantations have been cleared of bushes, and the land is being sown with Grass seeds to be fed off with sheep. This is not because the bush fruits failed, but because the Apple crop is so much more valuable that it is thought the trees should be freed from such root robbers. Thus set at liberty the surface-roots can revel undisturbed in the Grassy sward, and be constantly enriched by top-dressings. Under this treatment finer and cleaner samples of Apples are produced, and more money is realised without the bush fruits than with them. Of course, during the first few years, while the standard trees occupy but little space, the under fruit succeeds well and helps to pay expenses until the trees come into bearing; but the majority of cultivators of established orchards are daily becoming more in favour of a Grass crop over the roots of Apple trees; and, in addition to feeding sheep and other small stock under them, very few crops now repay a good rich manuring better than an Apple orchard.—J. Groom, *Linton Park*.

Pears in East Norfolk.—As information is solicited (p. 360) respecting the behaviour of Pears this untoward season, perhaps the following scrap from this north-east part of Norfolk may be interesting. On east walls the Jargonelles were scarce and inferior; the Suffolk Thorn is a good crop, but it ripens slowly, and the fruit has no flavour; Williams' Duchesse d'Angoulême is very good, but, as might be expected, rather smaller than usual; the flavour is, however, now delicious. It is a valuable Pear for all seasons and soils. Beurré d'Amanlis is good, but small and late; Beurré Bosc is good, and looks like ripening well; Marie Louise is a poor crop, and the fruit is small; Louise Bonne of Jersey mildewed and cracked, and so did Forelle; Passe Colmar, too, is much cracked; Winter Nelis is small and poor, and Beurré Diel is worthless. Uvedale's St. Germain is likewise small, and much cracked. Of Glou Morceau I have two trees on an east aspect; on the one on the garden wall the fruit is worthless, on the other, which is on a building with the eaves projecting 1 ft., the fruit is excellent, showing the value of a good coping. From a west wall a good crop of Doyenné d'Été was gathered in August. On the same aspect the fruit of Fondante d'Antonne is much mildewed and small; Josephine de Malines, on a south wall, produced an excellent crop of good clean fruit. On pyramids Beurré de Capiaumont has done well, as has also Vicar of Winkfield; I have never had the former better.—E. SENDALL, *Barningham, Norfolk*.

ANSWERS TO CORRESPONDENTS.

Mealy Bug on Vines.—Can you inform me how I can get rid of mealy bug, which is very bad in our Vineries. It is especially plentiful in houses in which our black Grapes are, rendering them uneatable.—J. W. S. [This is the worst of all pests that attack the Grape Vine, and strong measures are required to effectually deal with it. First of all well scrub with hot soapy water all the glass and woodwork, then limewash the walls, and as soon as the Vines are pruned remove all the loose bark; then well wash them with a strong solution of soft soap, taking pains to work it into every crevice, and a day or two after paint them over with a mixture consisting of 8 oz. of Gishurst Compound to 1 gallon of water, and a wineglassful of paraffin oil; add clay or cow manure to thicken the mixture and cause adhesiveness; afterwards remove the surface soil of the border, if inside, and replace it with fresh compost, or, if there be no border, thoroughly clean the floor with soapuds.—W. H.]

Spiræa japonica.—I have some *Spiræa japonica*, last year's seedlings, raised in the conservatory; to what treatment should they be subjected in order that they may bloom again in winter and spring?—A. B., *Norwich*. [After being forced they should be planted out on deeply-cultivated, well-enriched soil about 2 ft. apart, and kept free from weeds by frequent surface stirrings; during the growing season, should periods of drought occur, an unlimited supply of water and weak liquid manure should be given, as they delight in plenty of moisture at the root.—J. G. L.]

Fuchsias and Petunias.—What should be done with Fuchsias and Petunias which have done flowering in the conservatory?—A. B., *Norwich*. [Fuchsias that have done flowering should now be kept moderately dry and placed in a cool house, from which frost is excluded, until February, when they should be pruned and started in a very gentle heat. Petunias are best cut in a little at once and kept growing gently in an intermediate temperature; they will then supply plenty of cuttings for spring propagation, which will strike readily and make fine plants for summer decoration; the old plants may then be discarded.—G.]

Weeds on Lawns.—What is the best means of eradicating Wild Sorrel from lawns?—O. [The best way of getting rid of weeds of this kind is to loosen the soil with a fork and draw them out by the roots. Then sow some fine lawn Grass seeds and cover with fine rich soil, keeping it frequently rolled down firm. A dressing of soot and wood ashes will help to promote a luxuriant crop of fine Grass, as it is usually when this becomes thin through poverty of soil that noxious weeds flourish most.—L.]

Cyclamens.—I have some Cyclamens which were moved when in full bloom they come into leaf, but never flower. How can I induce them to bloom?—F. K. [Your Cyclamens are in all probability the commonly cultivated *C. persicum*, and if so, they should succeed under the usual treatment—that is, potting the plants in not too large pots in April, in rich light sandy soil, and growing them on in a frame till the end of the summer or later, when they should be showing flowers, and may be removed into a warm greenhouse to bloom. Afterwards the roots may be dried off till repotted in spring. Unless you are anxious to preserve the roots because of the associations connected with them you would have more success by sowing seed.—S.]

Seedling Camellias.—I have some Camellias raised from seed in 1872; they are now 3 ft. high, but never flower. Will seedling Camellias blossom?—F. K. [Seedling Camellias will bloom, but not so freely as grafted plants, for a time at least. To check their vigour they should be confined to small pots; but the speediest way would be to march shoots of the seedlings on named free-flowering varieties next spring. Inarching is easily effected, and it will enable you to prove in a short time whether your seedlings are worth anything or not.—J. S. W.]

Tuberose Culture.—I shall be glad of information concerning the cultivation of the Tuberose. I have one which has not flowered satisfactorily this year. It has developed young tubers, and it is for the future welfare of these that I feel anxious.—E. C. M. [In growing Tuberoses I find that they succeed best in a compost consisting of three parts turfy loam and one of sharp sand or road grit, leafsoil, and charcoal. I commence potting in the beginning of February, and keep on in succession until the end of March. I rub off the young tubers or offshoots, and pot firmly, the strongest singly and the smaller tubers three in a 6-in. pot. I then plunge them in Cocoa-nut fibre on a gentle hotbed, and give them plenty of air and but little water until they start into growth. I find them to dislike hard forcing. After they have thrown up flower-spikes they are removed to the Vineries and Peach house and trained to the back wall. Under this treatment we get a continuous supply of flowers from the end of May till December, each flower-spike producing on an average fifteen flowers. We use them largely for button-hole bouquets, for which they are indispensable.—J. C. M.]

Pears.—G. M.—Hacon's Incomparable is one of the good old Pears that used to be grown at Chiswick. It was raised by Mr. J. G. Hacon, of Downham Market, Norfolk.

Potatoes.—J. H. N.—The Potato which you have sent represents a by no means uncommon occurrence, of which there were fine examples at the last show of Potatoes at the Crystal Palace.

Names of Plants.—J. W. R.—*Coronilla Emerus*.—W. B. A.—1, *Adiantum Capillus-veneris laciniatum*; 2, *Selaginella uncinata*; 3, *Adiantum Capillus-veneris Moritzianum*; 4, *Onychium japonicum*.—M. L. D.—1, *Begonia incarnata*; 2, *B. Weltoniensis*; 3, *B. semperflorens*; 4, *B. Dregei*; 5, *B. Ingrami*.—A. K.—1, apparently *Jacaranda mimosifolia*; 2, *Syncarpia laurifolia*.—C. D.—*Quercus Lucumbana*.—P. M.—Probably a hybrid Ghent *Azalea*, as it is near *A. pontica* and *A. multiflora*.—M. W.—*Viburnum suspensum*.—Anon.—*Sedum carneum*.—H.—1, *Chironia decussata*; 2, *Dipladenia boliviana*.—G. Y.—The *Pelargonium* sent is *P. tomentosum*, the sport you speak of is a somewhat unusual occurrence.—A. R. W.—The specimens are more in number than it is our rule to name at one time; the numbers, moreover, were so insecurely adjusted that when they were unpacked there were but few of the tickets on the plants. Those bearing numbers were: 3, *Begonia semperflorens*; 7, *Begonia Rex*; 11, *Blechum lanceolatum*; 12, *Linaria Gymbalaria*; 14, *Ceterach officinarum*; 15, *Adiantum assimile*; some others we will answer next week. *Arbor*.—1, *Cornus sanguinea*; 2, *Liquidambar styraciflua*; 3, *Toxodermis distichum*; 4, *T. sempervirens*; 5, *Cotoneaster affinis*.—P. H. C.—1, *Onocidium varicosum*; 2, *Pteris longifolia*; 3, *Salvia splendens*; 4, *Adiantum cuneatum*; 5, *Lasiantha macrantha*; 6, *Pteris serrulata*.—R. S.—1, *Cotoneaster affinis*; 2, probably a species of *Clethra*, but cannot name without flowers.—P. & N.—We cannot identify the plant by the poor specimen sent.—S. T. D.—1, *Aster longifolius*; 2, *A. levis*; 3, *A. Chapmanii*; 4, *Boltonia decurrens*; 5, apparently fruits of *Cimicifuga racemosa*; 6, *Aster turbinellus*.—A. B. C.—Next week.—*Devon*.—1, *Adiantum*

Capillus-veneris; 2, *Asplenium monanthemum*; 3, *A. lanceolatum*; 4, *A. Trichomanes*; others next week.

Names of Fruits.—*J. P.*—West's St. Peter's. *Anon.*—The white kind is Foster's Seedling the other Black Hamburg. *J. L.*—1, Kerry Pippin; 7, Ribston Pippin; 11, Winter Pearmain; Pears—4, Crassane; 3, Brown Beurré; others next week. *M. C. R.*—Pears—Marie Louise; 2, Beurré Hardy; 3, Louise Bonne of Jersey. Apples—*J. T.*—1, Holland Pippin; 2, Cellini; 3, unknown; the Pear is Swan's Egg. *J. S.*—Apples—1, Golden Pippin; 2, Bleenheim Orange; 3, Ribston Pippin; 4, Cellini; 5, Holland Pippin. *R. F. C.*—Pear—Beurré Hardy; Apple—Golden Pippin.

Questions.

Gesneras Shedding their Corollas.—We have a number of Gesneras of the *Nagelia* type to all appearance in excellent health. The plants are about 2½ ft. high and almost perfect in form, but after developing one half of the blooms on their flower-spikes they refuse to open any more, the corolla falling off and leaving nothing but the calyx and the pistil behind, and so on the spike progresses. The plants are in 5-in. pots and well filled with roots. We have them in a minimum temperature of 60°, occasionally 65°, with fire heat. While they were making their growth we occasionally gave them a little weak liquid manure, but have almost withheld it since the blooms commenced to open. I am quite at a loss to know what can be the cause of the failure in question, and shall be obliged to any of your correspondents if they can help me to a solution of the difficulty. I may add that they went the same way last year, but the previous year they were beautiful and flowered to the extremity of the spikes.—**ENQUIRER.**

Pyramid Apples and Pears.—What sorts of eating Apples and Pears should I grow as pyramids? My soil is loam inclining to clay, and the situation rather exposed to wind at present. Can any one advise me?—**R. A.**

GARDEN DESTROYERS.

THE COMMON DAGGER MOTH.

(*ACRONYCTA PSI*)

THE common, or as it is known by some authors, the grey dagger moth, is another member of the family Noctuidæ, of which in these papers I have already drawn attention to four species. Its caterpillars, like those of the species already noticed, are at times, when in great abundance, very injurious to the plants which they attack; but instead of destroying kitchen garden produce and herbaceous plants, they feed on the leaves of fruit trees, White Thorns, and Roses, which they sometimes much injure by depriving them of their leaves. The common dagger moth, as its name implies, may often be found in great numbers, and in all parts of this country. When orchard trees are attacked by this insect the boughs should be well shaken, and a sheet or something of the kind spread underneath to catch the caterpillars on when they fall. As many as possible should

Acronycta psi and Caterpillar.

be picked off by hand. This can easily be done in the case of smaller trees and Rose bushes, as the caterpillars, on account of their size and coloration, may be found without any difficulty. The stems of the trees should be kept as free as possible from Moss and loose pieces of bark, and all cracks, &c., should be carefully examined

during the winter, as it is in these places that the chrysalides are generally found, and the destruction of one chrysalis will probably be the means of saving the tree from a brood of caterpillars. The moths begin to appear at the end of May or beginning of June, and then may generally be found plentifully till the end of August. There are probably two broods during the summer. The caterpillars are most abundant in August, September, and October, and in the last month, when fully fed, each finds a convenient crack or shelter of some kind on the boughs or stems of the trees, and spins a white cocoon, in which it undergoes its transformations, and appears as a perfect insect in the following May or June. The common dagger moth so closely resembles the dark dagger (*Acronycta tridens*) that

Caterpillar of *Acronycta tridens*.

it is by no means easy to distinguish the two insects when in their perfect state. This is, however, of little importance except to the entomologist, as the caterpillars of both species are equally destructive, and are similar in their economy in every respect; but they may, however, be easily distinguished from one another, as their markings are very different, as will be seen by the accompanying figures and the descriptions given below. The moths measure across the wings, when they are fully extended, about 1½ in. The upper pair are grey, with various blackish markings, by which this may easily be distinguished from the other species of this genus (except *A. tridens*). One of these dark marks is a branched longitudinal line extending from the base to nearly the middle of the wing. Near the lower and exterior angle of the wing is another, which is somewhat in the form of a dagger or the Greek letter psi, whence the popular and scientific names of this insect. Near the upper margin of the wing, and about the centre, is a dark mark, something like the letter x, between which and the end of the wing is a smaller dagger-shaped mark. The lower wings are nearly white, those of the females being rather darker than those of the males. In both sexes the veins are darker than the rest of the wings. The head and thorax are grey, with a black line on each side of the head, which is continued on the thorax just above the junction of the wings. The body is also grey. The antennæ are short, not toothed, and alike in both sexes. The caterpillars, when full grown, attain the length of 1½ in. The head is black, the body greyish-black, with a broad yellow stripe down the middle of the back, which is interrupted on the fourth joint by a high conical black tubercle, the point of which bears a tuft of hairs; and on the eleventh by a large hump; below this yellow band is a black one, which is ornamented on every joint but the first four by two red spots, separated by two whitish tubercles bearing black hairs; below this again is an ashy-grey stripe covered with grey hairs; this stripe becomes reddish as it approaches the foremost joints. The underside and legs are of a dingy flesh-colour. The caterpillar of the dark dagger moth (*A. tridens*) is of the same size as that of the preceding species. The head is black, but is so covered with grey hairs as to appear grey. On the fourth joint of the body is a large black tubercle, which is not nearly so high as in *A. psi*, and on the eleventh joint is a kind of hump with a white mark on the top; the intermediate joints have an interrupted orange band on their backs; the second and third joints have each a central reddish spot; below this on the joints which follow the fifth is a black band with three white and two reddish spots; beneath this stripe there is a yellowish-grey mottled band, with a yellow marginal line. The hairs on the body are long and silky, but not very numerous. **G. S. S.**

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FRUIT GROWING FOR PROFIT.

No one, I think, can look round the country without coming to the conclusion that there has been a good deal of haphazard work in orchard planting, and, as a matter of course, many of the trees have not, and never will, produce a satisfactory result. Many trees are too old, too exhausted, and in too neglected a condition to pay a fair rent for the space which they occupy. Many others, from having been planted in an unsuitable situation, or from not being prolific kinds, are in the same predicament. Still fruit culture is advancing, and it must continue to advance before it overtakes the demand, or, indeed, keeps pace with the increase of population. In commencing fruit culture for profit there are three main considerations that must never be lost sight of, as they are all essential to success. These are—1st, selecting the right site; 2nd, its proper preparation; and, 3rd, planting the right kinds of trees.

In the selection of the site of an orchard, the majority of planters have but little choice. Sometimes a lucky hit is made in selecting a sunny open situation on a gentle declivity facing the south, sheltered from the north and east; and wherever this is done, and the right kinds of trees planted, success invariably follows. In this country most of the villages and farmhouses are situated in dips or hollows. Occasionally a village may be found on the top of a hill, but not often; much more frequently it is nestling at its foot, with a stream of clear water running near or perhaps through its midst. Around the villages generally cluster the orchards and gardens, but I suppose few people require now to be told that these natural basins are just the worst places that could be selected for fruit trees. The cold, raw fogs and frosts come rolling down the hillsides in spring, settling in the low places, and killing every tender blossom of Apple, Pear or Plum tree that is fully expanded. Often trees on higher ground escape, when those in valleys are ruined. The breezy hillside is a far better situation for a fruit garden than a valley, even when the soil—which is generally the case—in the latter position is better in quality than that on the hillside. Somehow an idea seems to prevail that if fruit trees are not planted near some dwelling the fruit would not be safe; but I think this is a prejudice that actual experience would prove to be groundless. If fruit growing is to be made to pay in our climate the trees must be planted in the most suitable places, regardless of all minor details. It is necessary to live some time in any particular neighbourhood or district before one is competent to select a site suitable for a fruit garden. In one place the north or east winds are the most destructive. A few miles away owing to some peculiar conformation of the ground, the west and south-west blast bears down all before it; therefore, in selecting the site of an orchard on a large scale, not only must the character of the soil be considered, but also how it lies for shelter from the most damaging winds. Where planting is done on a considerable scale, shelter could be planted to break the force of the winds. A belt or copse of Larch and Hazel would quickly grow into an efficient shelter; but a few trees of a more permanent character should be planted with them, so that in the future, when the Larch has attained to a profitable size, and the Hazel stools are becoming exhausted, they may be gradually cleared off, still leaving a grove of Oak, or, if the soil were suitable, a handsome and effective shelter of Coniferous trees. This kind of fruit culture could, of course, only be carried out by capitalists; but the time may come when proprietors of large estates may have to turn their attention not only to the rearing of flocks and herds, but also to fruit growing on a large scale by way of making the most of their land.

Having selected the site and fully considered the question of shelter in all its bearings, the next thing to be done is to ascertain if the land requires draining, which may be done by sinking a hole 3 ft. deep, and leaving it open some time to see if the water collects or stands in it. The truth is, all land for fruit growing, unless on a gravelly or sandy subsoil, will be improved by draining, and it is useless to make the drains less than 4 ft. or 4 ft. 6 in. deep. The drains should be laid straight down the face of the declivity rather than across it; and the nearness of the drains to each other, and the size of the bore of the pipes, will have to be determined by the nature of the soil. In most cases 2-in. pipes should be used for the auxiliary drains, and not less than 4-in. for the main drains, always bearing in mind that the drains not only carry off the surplus water—which should be done quickly—but that they also help to aerate the land. When the draining is finished, the land should be

trenched or thoroughly broken up 2 ft. deep. If it lies convenient for the work the steam plough and cultivator may be usefully employed to smash it up, intermix, and pulverise it, especially where spade labour is expensive. Assuming that the land is naturally fertile, manure will not be required before the trees are planted. Any support which they may require, and that will be beneficial to them, can be given afterwards in the form of top-dressings and mulchings; these will keep the best roots near the surface, thus ensuring well-ripened wood and a fertile habit.

In selecting the varieties, none but those with an established reputation as regards free-bearing should be planted, and of these the most suitable can nearly be counted on the fingers. Early kinds of Apples and Pears that can be marketed without storing will often yield the most profit. Plums, where the land suits them, are generally a profitable crop, and they come into bearing sooner than Apples and Pears. In a large plantation of fruit trees, of course a good selection will include both early and late kinds, as, although the latter involve more expense, and frequently there is a longer time to wait for a return of interest for capital expended, yet the crop brings in more ultimately. The store-rooms must be dry and frost-proof, and fruit keeps best in the dark, as the temperature is usually more uniform and steady under such conditions. I have known dark dry cellars used for the purpose of storing fruit, and they have answered remarkably well. In private gardens there are commonly many varieties grown that are not profitable, so far as bulk of crop is concerned; but such kinds generally possess some peculiarity of flavour that makes it desirable to continue their cultivation. The man who looks for profit, however, would soon be ruined if he indulged in fancies. A large proportion of our orchards contain far too many varieties. It is impossible to be too particular in the selection of proper sorts, and a few days or even weeks, if need be, would be profitably spent in visiting the gardens and orchards within a radius of ten miles of the intended orchard, to see the kinds most generally prosperous, and to gather all possible knowledge respecting them. The whole matter of success or failure hinges upon the best kinds to plant; and when once we have received the conviction that any particular kind does well in any given district, then in that district it should be planted by the hundred. For fruit-growing on a large scale for profit I think the standard form, with a 6-ft. stem, is best; all other forms require more labour and skill in their management. Still some kinds of Pears do well as pyramids; Beurré de Capiaumont and Williams' Bou Chrétien, for instance, are especially fertile when not too closely pinched in. Treated as weeping pyramids they soon come into bearing, and their pruning or after-management gives but little trouble, as the heavy crops of fruit which they bear checks all tendency to over-luxuriance. In like manner some Apples are peculiarly fitted to form dwarf trees. Lord Suffield may be mentioned as a suitable subject for planting in beds of a hundred or more at only a moderate distance from each other. The kind begins to bear in a small state, and afterwards it bears so constantly that it seldom reaches a large size; therefore, to plant it wide apart would occasion a loss of space, unless the ground was occupied in addition with bush fruits. There is always a demand for Currants and Gooseberries, and they are not so liable to damage from bad weather as Raspberries or Strawberries, and as they generally yield a paying crop, every bit of space under tall standard trees should be planted with Red Currants and Red Gooseberries, as the demand for these colours is greater than that for others, with the exception of Black Currants; the latter is a profitable crop; indeed scarcely anything pays so well in damp corners; even if partially shaded by trees or buildings, they always thrive well.

The distances at which fruit trees should be planted from each other should vary according to kinds and soils, but a full grown standard tree of a free growing sort will occupy profitably a space of from 20 ft. to 24 ft. square. Dumelow's Seedling or Blenheim Orange Apples would require as much space, but Cox's Orange Pippin and Lord Suffield will be some time filling up two-thirds of that space. The same thing occurs in regard to Pears; those kinds that begin to fruit early, and bear crops annually, make less wood, and may consequently be planted closer together than others. Where all the space beneath or between is cropped with bush fruits, one may wait a little longer than they otherwise might be inclined to do for the top growth to fill up. Still any given tree can only occupy profitably a certain space, and, as some kinds will grow larger than others, it is wasteful to give the small trees as much room to grow in as the larger ones; therefore each kind of Apple, Pear, or Plum should be planted in beds or quarters by itself, both for convenience of allotting suitable space, and also for economising time when gathering the fruit.

The following are a few names of kinds that are good bearers in most places, but, as has been stated, local information should in all cases be obtained before planting largely:—Apples, Lord Suffield, Manks Codlin, Dumelow's Seedling, Blenheim Orange, Cox's

Orange Pippin, London Pippin, and Reinette du Canada. Pears—Hessel, Williams' Bon Chrétien, Williams' Duchesse de Angoulême, Benrre Diel, Knight's Monarch, Marie Louise, and Swan's Egg. Plums—Victoria, New Orleans, Magnum Bonum, Early Prolific, Diamond, and Golden Drop. Gooseberries—Red Warrington, Companion, Crown Bob, and London. Currant—Red Dutch, Black, Lee's Prolific, White Dutch.

E. HOBDAV.

CROPPING PEACH AND NECTARINE TREES.

THE majority of cultivators will, I think, agree with Mr. Cowburn's opinion (p. 424) as regards training, viz., that a line drawn between the two extremes is always the best, and I am certain that it is as applicable to cropping as to training. I have grown Peaches and Nectarines under both favourable and unfavourable conditions, and have seen many crops both light and heavy, but I can confidently assert that I never yet saw trees that would average ten fruits to the square foot. It could not possibly occur on a wall as there would not be space for large kinds like Noblesse to swell, as if the tree averaged ten fruits there must of necessity be some parts of it with twelve or fifteen to make up for the spaces occupied by main stems, leading shoots, &c., as no one ever yet saw a crop so equally and methodically distributed from base to summit as to be all alike; of course, on trellises one may crop on both sides, and it is by no means unusual to find ten fruits left to the square foot. I have, indeed, oftener erred myself in leaving too many than thinning sufficiently, and where I have drawn the line half way between what Mr. Cowburn and "J. S. W." consider a crop, and set the fruit out at the final thinning to three or four to the square foot, being guided, as "J. S. W." suggests, by the variety, I have had far the most valuable crop, as neither for the table nor for the market will quantity make up for quality, and the latter can only be secured by crops that the trees can finish perfectly.

Of course, if one were contemplating the removal of the trees after the crop is gathered it would be a different matter. Many experienced Peach growers would be satisfied with half the quantity of fruit which Mr. Cowburn calls a crop. I am at present planting a Peach house 50 ft. long, and shall be anxious to get as good a crop as possible; but it is so generally admitted amongst growers of Peaches and Nectarines that they do not answer to be gorged with rich manurial food like Vines, that one cannot well expect such an enormous strain to be borne with safety as that of a crop that would exceed in weight what is ever considered safe to put on a Vine, that will imbibe the richest of succulent food, and flourish on it. I am aware that there is a great difference between good and useful Peaches and the very best samples of the same kind that can be grown, and doubtless thinning the crop is sometimes carried to excess as well as leaving too heavy a crop; but I cannot believe that Mr. Cowburn's trees will maintain for many years such heavy crops as those recorded in THE GARDEN. If such a feat is possible, I must admit that what has been for years considered a good crop of Peaches or Nectarines must, by comparison with such results, be set down as little short of a failure.

J. GROOM.

Linton.

GROWING PEACHES ON THE EXTENSION SYSTEM.

IN corroboration of what "J. S. W." has, from time to time, said in your columns in favour of this system of training Peach trees, I may state that I this season saw at Brayton Hall a wonderful example of it in the shape of some Peach trees—maidens—which Mr. Hammond planted a few years since. They are already enormous trees, filling a great space with very fine fruit-bearing wood. On the old and barbarous system at one time practised, if not now in many places, it would have taken ten or twelve years to have built up such trees. Their stems were nearly as thick as a man's leg. I may also refer to a great many trees planted here in February, 1878, which, beyond being shortened back when planted, have not had a top cut off a twig since; some of them now are perfectly furnishing with wood spaces varying from 18 ft. by 14 ft. to 16 ft. by 12 ft., and they have carried a good crop of fruit this year.

D. THOMSON.

— Mr. Cowburn asked me (p. 372) for "information as to what is meant by extension," and he now complains that in answering him I illustrated the practice by comparing it with that delineated and described in the "Gardener's Assistant." It moreover appears that your correspondent did not require any information on the subject, for he knows both systems so well as to be able to tell us he "equally deprecates" both. That being so, I think it is my turn to ask a question or two from Mr. Cowburn. First, where did he try the "extension," the "restrictive," and the "something between the two" systems together, and what were the results of his experi-

ments that made him prefer the latter, which, let me say, I have less objection to myself? Secondly, I say that by the extension system in full you get a larger tree and more fruit in a given time than by any other method—that it does not interfere with the health or furnishing of the tree in any way, and that as much is proved by facts and experience. Is Mr. Cowburn prepared to meet this assertion with a direct negative, and substantiate the same by examples of practice? Answers to these questions will bring the matter to a direct issue, and that is what I desire. As to his assertion that Pears, Apples, and Crataegus pyracantha, &c., do not come under the same head, I have only to say that he is completely in error. The principle is the same exactly in both cases. What is a "cordon" but an extension-trained tree on a dwarf stock? The principle, when applied to Pears and Apples trained on the fan or horizontal system, consists in letting those limbs which are left extend at their extremities as fast as they will, never cutting them back at the winter pruning, as is recommended in most works on fruit culture. I call this "extension" to distinguish it; has Mr. Cowburn any other name for it? When the new walls enclosing the 6-acre kitchen garden at Thoresby Park were planted, Mr. Henderson trained his wall trees and espaliers on this extension system, and finer and more fruitful trees I never saw, nor any so large for their age, and they are there to be seen yet. As to Mr. Cowburn's ten good fruit to the square foot throughout I can only exclaim "Wonderful"! I do not expect ever to be able to produce a crop of "good" Peaches so thickly set on the tree as to touch each other, or very near it, nor do I ever intend to try. Ten "good" Peaches, but not what are reckoned extra fine, should at least cover 100 square inches, and as the interstices between the angles will nearly occupy the remaining 44 in. that make up the square foot, your readers may guess the rate of Mr. Cowburn's cropping, and wonder at the results.

J. S. W.

CLEARING PEACH TREES OF LEAVES.

THE practice of going over Peach trees in autumn with a light switch broom, or something of a similar character, that will remove the leaves that are nearly ready to fall on their own account, is often recommended and adopted both with trees under glass, and still more frequently in the case of such as are on open walls, the object assigned being to more fully expose the wood to the light and what little sun we happen to be favoured with when the season is so far advanced. But is the operation of any real benefit to the forthcoming crop or the trees in any way? This was a question that a good many years ago suggested itself to me, and, after reflection, I could not see of what benefit it could be, for it is a generally recognised belief that when the leaves of any tree have done their work and are ready to drop, the condition of the wood which has borne them, let it be satisfactory or otherwise, is beyond anything that can be done for it, so far as increasing its fruit-bearing capabilities is concerned. Take, for example, the Vine; if the wood is insufficiently ripened, not only when the leaves fall off, but if it is not fully hardened up when they begin to turn yellow, no exposure to light or sun, even with the aid of fire-heat, that I have seen tried has been of the slightest use. As left when the leaves have lost their power to further assist the wood, so it must remain.

Looking at the matter from this point of view, on several occasions, near a score of years back, when living further north, where Peaches do not in indifferent summers get so good a chance as they do further south, I tried the effect of removal by brushing off the leaves when they were in a condition to part from the wood. I did this with several examples of the same varieties, growing on the same wall with others that were left untouched, and in some cases I removed the leaves from one side of a tree and left those on the other to come off on their own accord. This I tried, as I have said, several seasons, but, just as I had anticipated, I could not see the least difference in the fruit produce of the ensuing summer between those which had their leaves all or partially removed and those untouched. The removal of leaves during the growing season has undoubtedly the effect of reducing the strength of the wood, and in the case of over-vigorous trees of any kind has an influence in diminishing strength proportionate with the extent to which disleafing is carried out. But this is a very different thing from expecting any effect as regards altering the condition of the wood and fruit buds already formed, and which, when the leaves are ready to fall, may be looked upon as beyond the influence of anything which the cultivator is able to do for them.

T. BAINES.

Swelling and Ripening of Pears.—At one time I was afraid that late Pears would be useless, but the following sorts have swelled up to a good useful size, viz., Marie Louise and Marie Louise d'Uccle, Olivier de Serres, Louise Bonne de Jersey, Beurré Diel, and Fondante d'Automne. These have been the best here.—J. C., *Farnborough*.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Hardy Pears.—In this northern district the fruiting spurs of many of the finer kinds of Pears were last winter so much injured by severe frost as to be quite black at the core, and consequently fruitless. Among those that withstood with impunity the vicissitudes of the abnormal period of frost and thaw which we experienced, none showed to more advantage than the old market garden favourite—Hessle. Of course, where fine fruit for table use is a desideratum, the sort just named would not prove of any great value; but where Pears are grown for profit, commend me to this variety. An extensive grower for market in this district informs me that out of 150 sorts of Pears planted for experiment, the Hessle and Marie Louise d'Ucele are the only sorts that withstood the severity of the winter with him; all the rest suffered from the black spot at the core of the fruit-spurs, while every tree of the sorts named bore fruit. Among Apples none do so well in the north as Hawthornden, which is a sure and certain cropper and an Apple of good quality.—TYNEDALE.

Grapes at Chiswick.—The friends and acquaintances of that excellent gardener, Mr. Barron, have been wondering whether a contemporary meant to be funny or complimentary when it published that ambiguous paragraph setting forth that Mr. Barron had managed to ripen the Grapes in the large Vinery at Chiswick by means of "fire-heat by day, and giving air judiciously added to the sun-heat, which the present open weather is affording!" Ripening Grapes by such means can hardly be considered a very wonderful circumstance, and we doubt if Mr. Barron is himself astonished at the result.—W.

Late Grapes.—The present season has been not only trying to the cultivator of Grapes up the period of ripening or colouring, but also as regards keeping them in good condition after they are ripe, as one hears of a more than usually heavy list of losses from mouldiness, which has this year set in much earlier than usual. This is doubtless attributable to the marked absence of sun-heat and excessive rainfall. Grapes have not been able to thoroughly ripen this year without a pretty constant assistance from artificial heat. I know that very fair samples of Hamburgh and other thin-skinned Grapes may be grown in favourable seasons without fire-heat, but their keeping qualities are always doubtful, and after such a season as the present it is not at all singular that Grapes ripened in the moist stagnant atmosphere that has prevailed so long (where means have not been taken to counteract its effects) are suffering more than usual. In our late Vineries, even in this southern part of the kingdom, we have not been able to dispense with fire-heat since the Vines were started in spring; just enough heat has been kept in the pipes to maintain a buoyant atmosphere, so that air might be kept on continuously, and the fruit looks like keeping as long as we may wish to have it. For the latest supply we have fortunately a great help in good sorts that do keep well, and any one wishing for good Grapes in winter and spring must not omit Lady Downe's, Black and Kempsey Alicante, Gros Colman, and Barbarossa, black kinds; and Muscat of Alexandria and Calabrian Raisin, white sorts. If these are ripened in a light buoyant atmosphere by keeping up a gentle heat, there need be little fear, I apprehend, of the result as regards the fruit keeping.—J. G.

Pruning Damsons.—During the last few years the Damson crop has become much more important than formerly, and many thousands of trees are planted annually in this neighbourhood, principally as an outer or sheltering row to orchards of more tender fruits, and in many cases they even occupy the hedgerows. During the late exceptionally wet summer they have made exceedingly vigorous growth, the leading shoots being mostly 3 ft. and 4 ft. long; these will be cut down quite low at the winter-pruning, and all the small spray-like growths left intact, as the Damson is proved to require pretty hard pruning to get good crops of fine fruit; if allowed to run up unchecked with long loose growths, even the best kinds produce comparatively thin crops as a rule; but when stopped so as to throw the energy of the tree into the weaker bearing wood, they become densely furnished with fruit-buds. During the present season I have had the opportunity of seeing many hundreds of young bearing trees, where the fruit hung quite as thickly as in the case of ordinary bunches of Grapes, for the Crittenden or Cluster Damson, now so largely grown here, sets three or four fruits in a bunch, so that in gathering, the crop may be taken off in handfuls. As the present is a good time for pruning, I would recommend any one having Damson or Bullace trees that have been neglected in that respect to at once shorten them in considerably, as dwarf compact trees are preferable in every way to those left to grow wild. They will quickly become furnished with spray-like bearing wood, when a crop of this useful fruit will be almost a certainty.—JAMES GROOM, *Linton Park, Maidstone.*

Cleansing Fruit Trees.—Autumn is the best time to cleanse fruit trees, and indeed all plants, from scale and other insects. Now fruit trees can be handled with less liability of breaking buds and spurs than in the spring after the buds have begun to swell, and the work will be as effective now as then. Use strong soapsuds. Apply it with a stiff brush; and do not confine the washing to the trunk, but go over all the small branches and everywhere on the tree where scale is found.—W.

Currant La Versailles.—This being the season when most people are planting fruit trees, it may not be out of place to add a note in favour of this Currant. All who want a showy Red Currant for dessert would do well to add this to their list. It is very large and of good colour and but little later than other early sorts. From some young trees of it this summer we had some of the largest fruit which I ever saw.—J. C. F.

Root-pruning Fruit Trees.—Root-pruning with the view of getting trees into a bearing state, will, I think, be admitted by many to be a waste of time and no gain, especially in the case of trees planted in heavy wet ground with a bad subsoil. Under such circumstances it is impossible to root-prune an ordinary sized tree without giving it a check that will prevent it from bearing a crop the following season; and in some cases, I have seen a tree after being lifted and root-pruned that did not show any signs of growth till autumn, when it commenced to grow and blossom, thus destroying all chance of fruit bearing for another year. Where trees are growing in light free soil the case is different, as they then make more fibrous roots, quite unlike the long bare roots produced in heavy soil; therefore in light soils root-pruning can be carried on without giving the trees such a check as they would experience in heavy ground. During these last few years we have been lifting a portion of our standard and wall trees every season, and I may state that we have a heavy wet soil to deal with; therefore before replanting we cut a main drain about 8 ft. from the wall, and in digging large pits for the trees, we cut two cross drains through the bottom of each pit, and run them into the main drain. We then cover the bottom of the pits with 6 in. of rough stones, and in some cases we use ashes, finishing with 1 in. of sand, and making all firm. We then commence to make up the pit with its natural soil, mixing it well as we proceed with sand, lime rubbish, and manure, and when half filled, another layer of sand is placed in it for the roots of the tree to rest on; then the pit was finished with the compost already mentioned. In this manner we have been successful in getting Apricot and Cherry trees to bear well, and over 100 ft. of a south wall border, planted with Peach trees, have just been treated in the same way. Hitherto neither Cherry, Apricot, nor Peach trees—although the best quarters have been allotted to them—have ever produced fruit that would compensate for nailing them to the walls. We had occasion to remove a Pear tree the other day that was planted and treated a few years ago in the manner just described; it had quite a mass of fine healthy young roots, close to the wall and not far from the surface, and to all appearance would have kept in a good bearing condition for many years without being disturbed.—D. MURRAY, *Culzean Gardens.*

Root-pruning.—I should not, as "J. S. W." suggests (p. 372), box off orchard trees; but, if I wanted to grow any special kind of wall or trained tree, I should rather curtail the root-space at first than have to endure biennial re-lifting, excavating, and all its attendant labour, simply because I never yet found such work to be remunerative. In this matter, however, every one must be guided by local circumstances. Many advocate root-pruning on the ground that it checks growth and promotes the ripening of the wood. That it will stop further growth I am well aware, but, as regards assisting ripening, I fail to see how a tree in a flagging, half-dead condition is to ripen its wood so well as if it had received no check. Root-pruning is simply a case of drying off or ripening off. My observations were intended to encourage the general reader to follow the example so profitably set in Kent to plant fruit trees largely of whatever kinds succeeded best in their own neighbourhoods. The allusion to the light, warm lands of the eastern and western counties was not likely to lead any one less imaginative than "J. S. W." to suppose that I considered Durham, Yorkshire, and the west of Scotland equal to Kent as regards fruit culture, but I know from a long residence in the eastern counties that the land is lighter and warmer than that of Kent, and the climate quite as good; and the western counties are certainly superior to the east for fruit culture. I could pick out quite as extreme cases in Kent as any "J. S. W." mentions; but here, if the land is ever so stiff, even bordering on clay, Black Currants are generally a lucrative crop, while Apples, Pears, and Plums are not very particular, provided the soil is strong enough, and where too light, poor, and stony for these, the Cherry thrives and proves remunerative. Other counties might be profitably planted with fruit trees as well as Kent. What we want is to shake off the notion that fruit-growing is a local Kentish industry.—J. G.

TREES, SHRUBS, AND WOODLANDS.

CRATÆGUS PYRACANTHA IN TOWNS.

Few plants appear to thrive better in the confined quarters of a thickly-populated town than this. Its vigorous and enduring character enables it to flourish in situations where most kinds of wall plants would either perish, or at the best linger out a miserable existence. It appears, indeed, to yield a richer harvest of bright, cheerful berries where the roots are somewhat cramped for space, the soil poor and liable to get very dry in the summer season, than where the roots can ramble freely in a rich, moist soil. The best berried specimen I ever saw was growing in a confined gravelled space in a thickly-populated town; it was thickly-covered with berries, and brightened up the narrow, dingy street most effectively during the winter months. Those who may have a piece of wall to cover in a situation unfavourable to wall climbers generally, cannot do better than plant the *Pyracantha*. It is neat in habit, may easily be kept within bounds, and will give satisfaction where scarcely any other plant will succeed. There is one point in its culture which is often overlooked, but which is of the highest importance. The tree should be gone over early in the spring of each year; where the branches are crowded, all weak, useless growth should be cut out, and the strong shoots laid in at regular intervals, so that sun and air may ripen the wood, without which the crop of berries will be but scanty.

It often occurs that specimens that have borne well in a young state produce no berries when they attain large dimensions, and many wonder that this should be the case. It would, however, on examination, be found that the branches have become so crowded and intermingled as to prevent their attaining the maturity indispensable to the production of a crop of fruit, for it should be remembered that the rules laid down for fruit trees generally apply to this *Cratægus*. Every branch and leaf must, as far as possible, be exposed to the influence of the sun's rays; and this result can only be attained by so training the shoots that each one is free from, and does not unduly crowd, its neighbour. I do not know of any other plant which better repays careful, intelligent training, and which at the same time yields so little satisfaction when unattended to in this respect. Not only does a regular distribution of the shoots improve the general appearance of the specimen, but the berries are in this way brought freely into view, and when each branch is studded at regular intervals with clusters of fruit, a large plant presents such a rich glowing mass of colour as is really not obtainable in the open air by any other means during the dull months of the year.

J. CORNHILL.

Hydrangea hortensis cyanoclada.—This is a handsome and distinct variety, and one which yields large heads of bright blue flowers. It is much the best blue-flowered *Hydrangea*, the colour being good. The leaves are of stout leathery texture and dark green. The stems are peculiarly black, and the leaf-stalks are also dark-coloured. This variety originated in Germany.

Leycesteria formosa.—This useful shrub has been growing here in a mixed shrubbery for more than thirty years, sheltered only by other shrubs and trees. Seedlings spring up in all directions, and bloom in a very young state, a fact which proves that it is tolerably hardy. Very strong shoots are best cut clean out, or very much shortened, no other pruning being necessary. I find it very useful in filling a vase mixed with *Fuchsias* of different colours and other flowers.—W. D., *Winton, near Maidstone*.

Large Chestnut Tree at Tortworth.—The following are the dimensions of the famous Chestnut tree here, viz.:—Circumference, 3 ft. from the ground, 49 ft.; spread of branches from north to south, 86 ft.; from east to west, 88 ft. These measurements were taken by myself about three weeks ago, and I can vouch for their correctness.—THOMAS SHINGLES.

The Maiden-hair Tree in Fruit.—"Prof. Sargent communicates the following to the 'Gardener's Monthly':—One of the *Salisburiæ*, planted some twenty years ago in the grounds of the Kentucky Military Institute, at Farmdale, and now 30 ft. high, proves to be a female, and has fruited this year for the first time. I am not aware that this interesting tree has fruited before in the United States, while in Europe specimens known to be female are still very rare. Its fleshy outer covering exhales an extremely disagreeable smell of rancid butter, but the kernel is excellent, with the flavour of Filberts, although more delicate. In Japan the kernels have reputed digestive qualities, and are very generally served as dessert. The cultivation of the 'Ginkgo' for its fruit is one of the possibilities of American horticulture, and is, perhaps, worth consideration." [We saw a very fine tree of it in the Vienna garden a

year ago, laden with yellow berry-like fruit, quite distinct, and even beautiful.]

Variegated Elms.—The broad and narrow-leaved variegated Elms should be accorded prominent positions in collections of hardy trees and shrubs. They are especially suitable for planting in shrubberies amongst Conifers and robust-growing evergreens, to which their clear fresh variegation affords a charming contrast. The small-leaved kind especially is very effective when thus employed; its neat, rather compact habit rendering it one of the best of variegated trees for small gardens. The variety named *Russleyana* is also an interesting and pretty kind, with small golden-hued leaves; it is but seldom seen, but is well adapted for planting in gardens of limited dimensions. Variegated forms of hardy trees and shrubs should be largely employed where there are extensive plantations and shrubberies; for often these latter consist of masses of common Laurels, *Rhododendrons*, *Thujas*, &c., which, although well enough in their way, are yet apt, when not lightened up and relieved by other forms of vegetation, to become monotonous and uninteresting.—J. CORNHILL.

Profits of Tree-planting.—It has been calculated that the tree thinnings of an acre of land worth only from 5s. to 10s. per acre, but planted with a mixture of Larch, Beech, Pine, Hazel, Birch, and Oak—the latter with a view to the growth of navy timber or trees of large size for building and other purposes—will at the end of from ten to fifteen years, according to local circumstances, repay the average expenses of planting, rent, and management during that period, together with compound interest at five per cent; and the profits of future falls may be estimated as follows:—In thirteen years, or at twenty-three years' growth, £24 10s. per acre; in thirteen years more, or at thirty-six years' growth, £39 per acre. After that period a triennial profit of about £12 per acre, until the Oak is fit for navy or other purposes, for which timber of first-class quality is required, when the final clearance may be expected to fetch from £200 to £250 per acre.—A. J. B.

The Sugar Maple.—This tree is found wild in Canada near the 48° of latitude, but is most abundant between the 46° and 43°. It flourishes best in a rich humid soil. In February or March, while the ground is covered with snow, the tree is bored to the depth of $\frac{1}{2}$ in. within the wood, with an augur about $\frac{3}{4}$ in. in diameter, and in an obliquely ascending direction, upon the south side of the tree, 18 in. or 20 in. from the ground. Two holes are made 4 in. or 5 in. apart. Tubes from 8 in. to 10 in. long, made of Elder or Sumach, are inserted to conduct the sap into troughs, which are capable of containing from two to three gallons each. The sap flows for about six weeks; four gallons yield 1 lb. of sugar, and from 2 lb. to 4 lb. is the produce of a single tree. The sap is boiled in sheds erected in convenient spots. Three persons can attend to 250 trees, which sometimes yield 1000 lb. of sugar. At the time when 80,000,000 lb. of sugar were calculated to be used per annum in the United States, it was estimated that one-eighth part, or 10,000,000 was furnished by the Sugar Maple.—B.

Furze as a Hedge Plant.—The common Furze does not generally attain its full size until four years old, and to make the most of it for lime burning and such like purposes it should not be cut oftener. It will upon poor land generally make a return of from 15s. to 20s. per acre. The soils best adapted to its growth are dry, sandy, or gravelly ones. It does not flourish well upon thin Heath or damp clay soils. Upon its favourite soils it makes a good hedge with proper management. The difficulty is to keep it thick enough for fencing purposes near the ground. By sowing it in three rows or tiers upon a bank, and afterwards cutting the first near the surface, allowing the second to attain a height of 2 ft. or upwards, and the third or uppermost row to grow to its full height, an almost impenetrable fence may be obtained. Duhamel in France, Evelyn in England, and Dr. Anderson in Scotland have extolled its merits as a fodder plant.—A.

Contrasts of Foliage.—Few better examples are to be met with than that afforded by the American Tulip Tree (*Liriodendron tulipiferum*) and the American Oaks, whose deep crimson shades at this season of the year contrast finely with the bright yellow of the leaves of the former tree.—J.

The Plane Tree.—The giant bulk and extraordinary beauty of the Oriental Plane Tree (*Platanus orientalis*) have made it in all ages an object of marked attention. Every classical reader is aware of the favour with which it was regarded by the Greeks and Romans, the latter of whom carried their admiration of this beautiful tree so far as occasionally to irrigate it with wine. The Turks in later days planted one at the birth of a son. In the court of the Seraglio existed a venerable specimen, planted by Mahomet the Second after the conquest of Constantinople, in commemoration of the birth of his son, Bajazet the Second. Forty years ago it was described as 50 ft. in girth. Another at Buyukdéri, on the Bosphorus, is described as

45 yards in circumference, but consisting of fourteen large trees growing from the same root-stock, coalescing near the ground, but at a short distance from it diverging into distinct trunks.—A. J. B.

Cratægus pyracantha crenulata.—This is now an object of great beauty on one of the walls at Chiswick. It is represented by a large and freely grown specimen literally clothed with berries that crowd the main shoots, and which are of a deeper colour than those of the common *C. pyracantha*. These will be in beauty all through the winter, but it has been found necessary to net the plant, as the birds have found out the berries, and are very fond of eating them.—R. D.

Yew Hedges.—One of the finest examples of a Yew hedge with which we have ever met is at Albury Park, the Duke of Northumberland's Surrey residence. It divides the kitchen garden from a portion of the pleasure-grounds, and runs in a perfectly straight line some 448 yards in length; it has, we understand, been planted 203 years. The individual plants have attained the size of good-sized trees; the top branches, if at all, had for a long time been little interfered with, and had extended a long way over the pleasure-ground side. Some years ago the bottom was getting thin, and showed signs of dying off. Mr. Kemp, the gardener here for over twenty years, set to work to remedy this, and had all these bottom branches cut in close to the main stems, at the same time shortening the upper ones to an extent that made 300 to 400 faggots, the result being that all the lower part broke freely, and as it is now kept clipped close in, presents an even wall-like surface to a height of 7 ft. Above this the upper growth has been allowed to extend at will; it thus forms a unique verandah-like densely covered walk, one of the most delightful promenades on a hot day, and being open on one side, there is plenty of light, and an absence of the smothering sensation often present under archways covered closely in with dense growth. This grand old hedge at Albury affords a lesson worth the consideration of those who have screens or hedges of this tree. We often hear complaints of Yew when thus employed after a lapse of years dying off more or less in places without any perceptible cause, but, although generally unobserved, we have no doubt that previous to death gradually less and less annual growth had been made, the plants ultimately succumbing to the weakening influence of over-restriction. Death in this way usually occurs when the hedge is kept clipped so as to allow very little breadth, for we have never seen it happen where enough width existed, even when kept low.—“Journal of Forestry.”

Hydrangea paniculata grandiflora as a Standard.—A good deal is said now-a-days about the attractiveness of the standard form of this *Hydrangea*. The oddity of the form doubtless constitutes one of its attractions, but another may certainly be found in the fact that this form of growth brings out the effect of the flowers more prominently. It prevents, likewise, both foliage and flowers from being trailed and beaten into the ground. One objection made against the standard form is the crooked shape which the stem generally insists on assuming. Viewed in another way, moreover, the standard form is unnatural—not adapted to exhibit the true habit of the plant grown under favourable conditions. If, therefore, the standard form is employed at all, a short or low stem should be accepted as the most practical and appropriate to the so-called tree *Hydrangea paniculata grandiflora*.—*Rural New Yorker*.

Pruning Fir Trees.—The best way to remove the long bolt-like insertions which the dead branches of Fir trees leave upon their trunks is to select a frosty day early in the winter, and go through the plantations armed with a short stout bludgeon, first gently loosening the stumps of these dead branches, and afterwards dealing them a smart blow sufficient to break them off inside the bole, when they can be easily withdrawn. But when the lower branches are dying back, and decay has not yet reached the trunk, they may be pruned off close in the same way as hardwoods. As the branches of these trees grow in whorls or tiers, so that the weakness arising from dead or cork knots is more concentrated or localised than in hardwood trees, it becomes the more necessary to attend to the early removal of dying branches, so that as the trees increase in diametric bulk the wounds may heal over, and the continuity of the grain be restored.—A. J. B.

Ivy on the Stems of Lawn and Pleasure Ground

Trees.—It is often supposed, and with justice, that Ivy is a dangerous interloper amongst the branches of trees; but it is so very beautiful to see the trunks of trees covered with the handsome leaves of this best of evergreen climbers that very much more may be done and should be done to show it. There is no way in which more graceful beauty can be added to many lawns or other grounds bare of trees than adorning their trunks with the different kinds of Ivies. It is quite easy to keep them within control so that they shall not mount up and choke the tree. To cover the trunks to a height of 12 ft. or 15 ft. with the glistening foliage of this charming plant is a delightful improvement. Whole collections of Ivy might be grown in this country successfully in this way, and much more satisfactorily than on walls. A little care would be necessary in culture if they are to do no harm and look well. The Ivy would form a kind of carpet, so to speak, on the trunk, and should be encouraged to do so by annual pinching. At the same time it might be reduced at the top in case of getting too vigorous. Some of the small-leaved kinds look very beautiful on tree trunks, and so do the large ones by contrast with them. Our illustration shows, imperfectly it is true, several trees covered with Ivy in the Champs Elysées. The trees do not appear to suffer from it in the least, and the effect is at all times charming.

Ivy on the Stems of Trees.

Cistuses or Rock Roses.—In last week's *GARDEN* (p. 419) are a few remarks about *Cistuses* or *Rock Roses*, in which the writer speaks as though *Cistus cyprinus* is only a variety of *C. ladaniferus*, whereas they are totally distinct plants. *C. cyprinus*, or common Gum Cistus, is the one which is now erroneously grown and sold at nurseries as *C. ladaniferus*, whereas *C. ladaniferus* is quite distinct. Sweet in his “*Cistineæ*” remarks “This beautiful plant must not be confused with the plant generally known by the name of Gum Cistus in the gardens, and also confounded with this in *Curtis's “Botanical Magazine,”* t. 112; the plant there figured is *C. cyprinus*, of M. de Candolle's “*Prodromus*,” and differs from the present in bearing three or more flowers on each peduncle; the leaves are also petiolate, and the capsules only five-locular—differences which readily distinguish it from our plant, which, we believe, is the largest flowered species of the genus. It is not so hardy as *C. cyprinus*, and will not survive our winters in the open air, except very mild ones.” From these remarks we see that *C. cyprinus* has three or more flowers on each stem, whereas *C. ladaniferus* has only a solitary one, which

is very large. There are two forms of this, viz., *albiflorus*, which has large pure white flowers, and *maculatus* is white with a large blotch at the base of each petal.—R. POTTER.

Sprouting Locust Seed.—The practice of scalding the seed of the common Locust to induce germination is well known. A correspondent states that he could never make more than one in twenty grow before he adopted this process. After the hot water is applied, a portion of the seeds are found double in size; these are selected and planted, and the process repeated several times till all or nearly all are made to germinate. Without this treatment the seed might lie in the ground for a century.

LEAFLETS.

It is rarely now-a-days that a really good book on horticulture is produced; therefore, I have all the more thoroughly enjoyed turning over Leroy's excellent "*Dictionnaire de Pomologie*," which is unmistakably a great book and a fitting monument of a well-spent life. The subject, style, and treatment are in all ways excellent. In plan, execution, and practical information the work is far before anything attempted on fruit in this country. To translate such a work would be a very onerous task, and it is scarcely to be desired, unless some one like Mr. Barron, at Chiswick, would undertake to adapt it to our own wants, and graft English experience upon it. Happily the information is easily accessible in French.

Among fruits we have little novelty this year—a year in which our commonest hardy fruits have failed to ripen—but good judges speak well of Belle Julie, an October and November Pear, which is all the more valuable from coming out so well this bad season. It may be added that it is a very bad year for naming fruits, as many of the kinds have not attained their usual proportions, colour, or flavour.

I hear that many of the Peach trees in the open air at Goodwood are dead or dying, owing to the cold, wet, sunless summer which we have had. The same fatality has also occurred in other places, a circumstance which has a depressing influence to those who love to see the Peach well grown in the open air. In ordinary times the Peach suffers a good deal in inland and cold districts, and the fact is that it is a tender tree, and one which, when grown out-of-doors on walls, requires a little more protection and attention than it generally gets to save it from the winter and spring severities; but when the destructive cold comes in June, as this year, one is driven to despair of outdoor culture.

A great divergence of taste is exhibited on the subject of "button holes." Some noble and enthusiastic patrons of horticulture wear these every day in the year, and have them sent after them by post wherever they go. They are of the commonly approved pattern, and usually consist of one large flower, of overpowering odour, flattened out to its greatest diameter, backed with Fern, and attached to an Oak-leaved Pelargonium leaf, nearly as large as the lapet of a dress coat. Considerable engineering skill is exhibited in the construction of these ornaments of the person, wire is not spared, and the weight of that alone would handicap the wearer in a race. I have seen a lady prepare a pretty contrast to these by plucking a single Rose-bud off the tree, and placing it in a three-lobed Rose-leaf from the same bush, and of other equally simple materials arranged without wire.

It is advised, I see, to extend tree planting on waste lauds, in order to compensate our agricultural losses, and no doubt the advice will be followed by landowners who have often a hobby in that direction. It might be well to enquire first, however, whether an extension of our forest area is likely to improve our already dripping climate. I suppose it is proved beyond a doubt that trees increase the rainfall, and it is questionable therefore if any extension of our woodlands is desirable. I doubt if any other country in Europe is so evenly and well furnished with woods as our own, or has such a copious and evenly distributed share of the rainfall. Farmers grumble already at the unnecessary quantity of hedgerow timber in their fields, and would advise cutting down instead of planting, if they had their will. It can hardly be doubted that a reduction of our forest lands would give us a drier climate.

Although a disciple of Mr. Darwin myself, at least, to a very great extent, I fear that a good deal of speculation connected with his theories is extremely doubtful science—the insect-eating plant theory for example. I was going through Mr. Bull's house the other

day, at Chelsea, and saw therein numbers of the Pitcher Plants very seriously injured instead of "nourished" by the flies that entered the pitchers. The common bluebottle enters and dies in the pitcher; soon after the part immediately around where the flies rest decays; eventually this decay spreads and kills the leaf or Pitcher. Here there are numerous instances of this state of things, and they show the poisonous effect of the decaying flies on the sensitive surface of the leaf. The loss is a very serious one, even although the greatest pains are taken to exclude the flies from the house. So much for insect-eating plants. For my own part I never could see anything more remarkable in a plant absorbing animal matter by one surface than another—by the stem than by the root. The feeble illogical writings we have seen on insect-eating plants are certainly no gain to knowledge.

Referring to the Cardinal-flowers mentioned last week, I find that Mr. Bull, of Chelsea, sent out a great many valuable varieties about fourteen years ago, and that most of them now are probably lost to cultivation. A sad catalogue could be made of plants thus lost; species one may hope to find sometime in a wild state, but varieties are, in many cases, doubtless wholly gone.

I find Mr. Barron, of Chiswick, to have the same opinion as to the Chasselas Grape as that which I expressed last week, viz., that it is the most grateful of all kinds. He also speaks very highly of Gros Maroc, a Grape which I believe is now in fruit in Mr. Rivers's collection at Sawbridgeworth.

Mr. R. Harrison Weir tells me that he has succeeded in ripening the Champion Muscat Grape in a ground Vinery. It is probable that sometimes success would be obtained in these little contrivances when the fruit might fail in larger structures. He praises this Grape very much, and says he has been most successful with it in hothouses, cool houses, orchard houses, and ground Vineries.

Mr. Shirley Hibberd shows his versatility once more by attacking the water question. He thinks, and with good reason, that it might be simplified very much by people carefully collecting and storing the water which falls on their houses. Given a clean surface to receive it, and perfectly clean storage tanks, I can conceive no plan more excellent than having a good supply of water, which might be without a trace of impurity. His pamphlet is published by Effingham Wilson, of the Royal Exchange.

I hear that that noted traveller and author, Sir Samuel Baker, now or lately in our new possession, the Island of Cyprus, considers the Grapes grown in some parts of the island to be quite equal to our English hothouse Grapes, which does not speak ill of that much abused climate.

Mr. Henry Trimen, of the British Museum, has been appointed Director of the Botanic Gardens, Ceylon. The authorities are to be congratulated on obtaining as successor to Dr. Thwaites and Dr. Gardner, a thorough botanist, and one to whom the very important charge in question may safely be trusted. In such a happy garden isle the botanic garden must be a paradise as regards plants, and we fancy a visit to Dr. Trimen in Peradeniya will be even more pleasant than it was in the stately building in Bloomsbury.

I hope a good man will get the Epping appointment, and one in all ways fitted for it. Unhappily, these City Corporation appointments are often supposed to be influenced by jobbery. The place is one of those which should go to a tried man brought up to the forestry and nobler phases of gardening. Epping Forest properly managed and planted with perfectly hardy trees and shrubs only, would be a national garden in an higher sense than anything I know of at present.

I forget who was responsible for glazing the big Fernery at Kew with glass of a dark bottle-green, but the thing is a complete mistake. It does nothing in the hot summer which could not be effected by other and simpler means, and is injurious to the plants throughout three parts of the year. The countenances of the young men in this structure form an interesting if not very agreeable study—all as green as a dying Fern.

"Good natural methods of teaching—more attention to public gardening—would do much to instruct the people properly. Why should not (as a writer in the *Country Gentleman* remarks) the Geneva cemetery be a scientifically arranged arboretum and herbaceous ground, with the plants grouped after the conspectus of alliances in Bentham & Hooker's *Genera Plantarum*, for instance?"

Can any one tell me?" Yes, the probable reason is, my friend, that nobody in your neighbourhood had the power to do a very foolish thing. Books may be made thus—not beautiful or instructive gardens, and for reasons that have been stated often in THE GARDEN. Have all the beautiful and distinct things you can, and place them where they will grow best, and how they may look most beautiful.

*

The state of the great Palm house at Kew is at present thoroughly satisfactory. Considering the difficulties of the very artificial cultivation therein carried on it is surprising what fine effects are obtained. A good plan has been the covering of the borders with Ferns and various low-growing plants, and the training of a variety of graceful plants up the stems of the Palms and other large subjects. Indeed, there is scarcely anything to be desired unless it be the concealing of the pots at the edges of the beds. The narrow box filled with Moss does not conceal them, it only shows a stiff and poor attempt to do so.

*

Referring to the new garden at St. Paul's, the *Graphic* says: "The change, however, though so desirable, has been a costly one, no less than £5000 having been spent in making the alterations and additions; and the outlay necessary to keep the gardens in order will, it is thought, exceed £400 a year. This to many will naturally appear a very large sum, but it is said that those who understand such matters do not consider it exorbitant." Well, it does seem to me that the sum is exorbitant, and if this sum was spent wholly in gardening it is simply scandalous. It is lamentable that there is a good deal of what one would not like to apply a name to in the various efforts made to improve the public gardens of London. Of course anybody who knows anything about the matter must know that very few trees will grow round St. Paul's, and these not expensive ones. In addition to trees, all the place demanded could not be very costly. The finest gardens in London cost very little to make and very little to keep. Such, for example, as Berkeley Square. The planting of evergreens round St. Paul's, to perish in a year or two, is bad City gardening. The worst of it is that this waste of means, while it may benefit a few individuals, really eats up the force that might be employed more profitably for the embellishment of the many spaces yet in London that require planting.

*

A correspondent writes: "I have just returned from Seilly and Cornwall, where I have been taking my holiday. What a fine place Tresco Abbey is! I had a great treat there; I found several *Agaves* 25 ft. high in flower, and in the open air such plants as *Dolichos lignosus*, *Lapageria rosea*, *Rhynchospermum jasmoides*, and, in fact, a whole host of New Holland plants, such as *Dicksonia antarctica*, *Alsophila excelsa*, *Cyathea medullaris* and *dealbata*, just now only slightly protected; also *Escallonia montevidensis*, *Pittosporum Tobira* (with white scented flowers), *Acacias* full of bud, and the true *Dracena indivisa*, with beautifully striped leaves. Rockwork is a very prominent feature there, and one of which the late Mr. Augustus Smith was very fond. *Banksias*, and indeed many plants not common elsewhere are luxuriating there; *Brugmansia sanguinea*, arborea, lutea, and Knighti look well, and of *Phormium tenax* there are quite thickets."

*

I call the following obituary blossom from a contemporary: "Recently, Mr. George Gordon, A.L.S., for many years connected with the gardens of the R.H.S. at Chiswick, and author of the 'Pinetum.' Although a man of experience and good judgment, and possessing a very extensive knowledge of trees, he had long ceased to be in any way interesting, either to those who knew him personally or those who knew him only by his labours and associations. The truth is, he was so morose, reserved, and wanting in all that constitutes an agreeable sample of humanity, that long ere he parted from the world he was almost completely forgotten." So we have not one ghoul-erie of poor Gordon, but two. If such things are said uninvited, it were surely as well to say them while the person to whom they refer is alive. As a friend writes, "throwing mud at a corpse is dreary work."

*

I bought the other day at Warren's shop, in Jermyn Street, what was said to be an Australian Apple, and it is the first I have seen in a London fruit shop. It is very like the Wellington when in perfect condition. It came packed in a long box in Oat husks, quite different from American packing, and free from bruise, such as the American fruits often have. The flavour smacked a little of the packing material, but the flesh was perfect. With the increase of fruit culture throughout the world, our Apple supplies will some day no doubt be continuous throughout the year. New Zealand or Tasmania ought surely to equal or beat America, and they might supply us at a different season.

A friend writes as follows: "'Leaflets,'" he says, "is a fresh and workable idea—very comprehensive, makes a place for the wider phases of garden knowledge, and will be of interest to many if really well done. I observe that the gardening papers generally are crucibles in which thoughts too often become molten to a dead level. If gardeners would but learn to write as knowingly and lovingly of their plants as Buffon wrote on animals and Michelet wrote on birds, readers might be comforted and cheered instead of wearied. All this is difficult to be brought about, but a 'gossipy' style can often be made to do duty for a really learned and original one. Perhaps the best of all ways of writing of plants for gardeners to adopt is to say as much as they know of the plant in as little space as possible. They would thus go straight to their mark. 'Wobbling' is the bane of horticulturists when they take to the pen, and, perhaps, learning how not to 'wobble' is the great end of all learning." JUSTICIA.

EVERLASTING FLOWERS AND GRASSES.

THE scarcity of freshly cut flowers during the dull season of the year, and the increasing inherent desire for floral embellishment, particularly at Christmas time, has led to the development of an enormous trade in preserved flowers and Grasses, and the bright hues with which they are dyed (though in some instances unnatural), and their elegant appearance render them a capital substitute for fresh blossoms. This demand has not only been the means of increasing the extent of the trade as regards quantity, but every available source has been laid under contribution in order to bring into requisition as much variety as possible, and though there is already a great number of subjects employed, there are probably many others which could be advantageously introduced for the purpose. An adequate idea of the extent of this branch of industry may be formed by a visit to the extensive factories and warehouses in the immediate vicinity of Covent Garden Market, belonging to Messrs. Hooper & Co. Here may be seen in operation the various processes to which the material is subjected, from the cleaning, bleaching, dyeing, and drying rooms to the commodious workrooms, wherein are employed scores of persons who manipulate the flowers and Grasses into bouquets and other devices with remarkable artistic skill. The greatest demand for these flowers is towards the close of the year, and the enormous number required of bouquets alone is almost incredible. They amount to more than 100,000 a season, and a ready market for them is found in the great manufacturing centres.

The flowers and Grasses employed for this purpose are grown chiefly on the Continent, where a large extent of land is devoted to the production of these alone, from whence immense quantities are sent to this country. Of flowers, the majority consist of species of the vast family of Composites, and chiefly those on which the flowers are enveloped in scale-like leaves of a dry chaffy character, these being very persistent and retain their colour a long time; hence they are termed "everlasting." Amongst these the well-known *Heliopsis bracteatum*, which is a fine ornamental annual, is largely used, its flowers of varied hues being admirably adapted for the purpose. The pretty yellow-flowered *H. orientale*, too, is largely grown, and constitutes the French *immortelle*; likewise *H. margaritaceum*, *H. fetidum*, and *H. compositum*. The *Xeranthemums*, too, with their silvery-white flower-heads, the blue and white *Catananches*, the pretty pink *Acroclinium* and *Rhodanthes*, the white *Ammobium*, *Gnaphalium*, and others, all find a place in these winter bouquets. Various kinds of *Statice* are also made use of, such as *S. sinuata*, *S. Bonduellii*, *S. scoparia*, *S. Limonium*, and other sorts, and the appearance of the numerous tiny flowers on intricately branching flower-stems render them very elegant in combination with others. The leaves also of the Silver Tree (*Leucadendron argenteum*) is also largely used in the composition of crosses, wreaths, &c., and their silky-white surfaces have a very pretty appearance when intermixed with flowers.

Besides flowers which are dried naturally, there are many other kinds dried admirably by a particular process, so as to preserve their forms and colour. These include *Roses*, *Pansies*, *Carnations*, *Sanvitalias*, *Asters*, and various others; and the effect which they produce when skilfully arranged with others is very pleasing and scarcely less inferior to freshly gathered specimens, as far as appearance is concerned.

The Grasses comprise a great bulk of the trade; those mostly used are the feathery *Stipa pennata* (which is imported from South Europe by the ton), the Hare's-tail Grass (*Lagurus ovatus*), the various kinds of Quiver Grass, the elegant *Agrostis pulchella* and *A. nebulosa*, *Uniola paniculata*, *Bromus briziformis*, *Melica altissima* and *M. ciliata*, various *Avenas*, *Pennisetum longistylum*, and last, but not least, the splendid plumes of the Pampas Grass, *Arundo conspiciua*, and *Andropogon formosus*, which is obtained in large quantities from Florida.

Another important branch of business that is carried on in this establishment, but which does not come within the scope of our present remarks, is the manufacture of artificial flowers, and also of porcelain *concomres*, for mortuary purposes, which of late years have come into public favour. In the case of the artificial plants and flowers, there is in many instances a remarkably correct imitation of nature, whilst in others it requires a considerable stretch of imagination to identify them with the plants they are supposed to represent. Begonias, Caladiums, Aralias, Dracenas, and fine-foliaged plants are the happiest productions in this way, and they are certainly very artistically designed. W. G.

THE INDOOR GARDEN.

FLOWERING FERNS.

(ANEMIA.)

SEVERAL genera of Ferns are characterised by having their spores disposed in spiked or branched clusters on separate parts of the same plant, either attached to fronds with barren leafy segments, or upon specially-adapted fronds, whose leafy portion is almost entirely absorbed in the production of spores. Though the colours these clusters assume are never very showy, being either green, yellow, or brown, yet they bear such a close resemblance to the inflorescence of flowering plants, that this singular arrangement has given rise to the popular name of Flowering Ferns. The *Osmundas*, *Onocleas*, *Aerostichums*, and *Anemias* are among the best known Ferns which exhibit this peculiar structure. The genus *Anemia*, into which the genera *Anemidictyon* and *Coptophyllum* have been sunk—the former differing from the true *Anemias* by its reticulated venation, and the latter by its distinct barren and fertile fronds—contains upwards of thirty good species and several well-marked varieties, which are chiefly confined to Tropical America, only three being found in the Eastern Hemisphere, viz., *A. Dregeana* in South Africa, *A. Wightiana* in Hindostan, and *A. Schimperiana* in Abyssinia. The two latter are said to be varieties of the variable species *A. tomentosa*, described at some length below.

The annexed figures will give a clear idea of the structure common to the whole genus, exclusive of *Coptophyllum*, alluded to above. The fertile fronds represented are seen to be divided into three parts, the leafy portion of which is exactly similar to a normal barren frond, consisting of several opposite pinnae, decreasing in size upwards. Below the lowest pair the fertile divisions originate, and rise perpendicularly when the frond is in its natural position; the upper portion of these on examination is found to consist of several deeply-incised pinnae, with their leafy portion so much reduced as to leave nothing but the ribs, which are incurved at the points, and their inner surface thickly studded with minute ovoid spore cases. In habit all the known species closely resemble each other, but their foliage presents every variation in cutting from the entire pinnae of *A. Phyllitidis* to the finely-cut foliage of *A. millefolium*, a species not in cultivation. The fertile divisions occupy the same position in all the species of this section, excepting in a few instances where the barren portion is stalked instead of being sessile, as is shown in the figures, and they are the least variable of any of the parts of the plant. The majority of *Anemias* grow freely from spores, especially the *Phyllitidis* group; but the others, though they germinate quite as readily, frequently die off in the prothallia state, if the moisture be in excess. To remedy this, it is better to sow the spores upon nodules of rough peat or pieces of Fern-stem, so as to ensure good drainage. Some have creeping rhizomes, and can be increased by division, but propagation by spores is the most expeditious method. A soil composed of equal parts of light loam and sandy peat is the

most suitable for all the robust kinds; but the tenderer subjects require a light spongy soil, almost entirely of peat, or with an addition of good leaf-mould. They require ample drainage and only a moderate supply of water; but a dry state of the soil should be guarded against. The glabrous forms of *A. Phyllitidis* may be grown with advantage in the shade, but full exposure to light is essential to the variegated and all the pilose and tender kinds; and care should be taken to keep the foliage clear of dripping water, as a constant wetting of the foliage not only causes its disfigurement by turning it black, but greatly injures the plant.

The *Anemias*, being chiefly tropical in distribution, require the temperature of a stove or intermediate house, and an airy

Anemia Phyllitidis (fertile frond half natural size).
a fruiting portion; b barren portion.

situation. Very few of these interesting Ferns are as yet in cultivation, and the gems of the genus still remain to be introduced from their headquarters in Tropical America. The following selection contains the best of those already established in our gardens.

A. Phyllitidis.—The best known of the genus, growing to the height of 12 in. to 24 in., inclusive of the fertile panicles, with numerous, spreading, pinnate, barren fronds with a triangular-ovate outline, each consisting of from eight to ten pairs of sessile, ovate-acute, serrated, glossy-green pinnae, which are invariably inserted oppositely; the terminal one is usually similar to the lateral ones, but not unfrequently it is trilobate. The stipes of the fertile fronds are much longer, as a rule, than those of the barren, and are much more rigid and erect. The spore-bearing panicles, which are at first green, ultimately change to an orange-brown. Several varieties of this species are known, which by some are considered species, but they differ so slightly in structure from the species in question

that it seems most fitting to define them as permanent varieties. The principal of these are: *A. tessellata*, which has broad lateral pinnae, and a terminal one, which often exceeds all the rest in dimensions; it however differs from the type mainly in colour, which consists of a groundwork of yellow, overlaid with a network of green veins; *A. angustifolia*, a slender plant covered with fine setaceous hairs, and differs from the other in having bluish-green, narrow, wavy pinnae, with tapering points; *A. fraxinifolia* is likewise a very robust plant with fewer fronds than the type, and distinctly sagittate pinnae in a young state, which become coriaceous and deeply veined when old; and *A. densa*, also a compact-growing plant with numerous narrow-pointed, closely-arranged pinnae, often over-lapping each other at the margins. This group occurs commonly in the West Indies, and southward to Brazil.

A. mandioccana.—Independently of the ornamental panicles, this is a remarkably handsome Fern. In habit and form of its

Anemia tomentosa (fertile frond half natural size).

pinnae it bears some resemblance to *Asplenium alatum*, but has more prominent veins and a firmer texture. The fronds are lanceolate-acute, inclined to triangular, and about 12 in. to 15 in. in length, raised on pilose stipes, those of the fertile fronds being the longest. The pinnae, which gradually decrease in size towards the point of the rachis, usually over-lap each other at the margins, which are entire on the lower half of each pinna, and recurved and crisped on the upper half. The branchlets of the fertile panicle are very slender, and more inclined to spread than in the foregoing. The dark glossy green and permanent freshness of its foliage render it a very desirable Fern. It is a native of Brazil.

A. collina.—Two *Anemias* are cultivated under this name; one a mere variety of *A. Phyllitidis*, and the true one, which partakes of the character of *A. mandioccana*, agreeing with it in dimensions and the outline of its fronds, but differing in the colour and form of its pinnae, which are light green, and inserted further apart upon the rachis, which, like the stipes, is thickly clothed with orange brown hairs. The pinnae are oblong and unequal sided, and number from eight to ten on each side of the rachis. The panicles, which rise

several inches above the foliage, have numerous erect, close branchlets of a lighter green than the foliage. Though not quite so elegant as the preceding, it is still a very attractive plant. It also is a native of Brazil.

A. Breuteliana.—This has a short creeping rhizome, and grows in tufts composed of several crowns. The barren fronds, which are triangular and pinnate, rise to the height of a foot or more, with several pairs of oblong sessile pinnae, which are frequently lobed or pinnatifid. The barren segments, as well as the entire fronds, spread horizontally, while the fertile panicles, which have slender branchlets, rise some distance above them, a feature which, combined with the soft green, downy foliage, adds greatly to its attractions. A native of the West Indies, Mexico, and Peru.

A. hirsuta.—A very slender species, which in some respects is not unlike the preceding, producing a quantity of grayish, downy foliage from a tuft of small crowns. The barren fronds are triangular, with from six to eight pairs of deeply pinnatifid pinnae. The fertile divisions, which rise about 6 in. above the barren fronds, are surmounted with short compact panicles. This is a common Tropical American Fern.

A. tomentosa.—Of the large group with much divided fronds, this and the variety *cheilanthoides* are the only representatives in cultivation, though the forms are widely distributed, as well as being very variable. The barren segment in the figure represents a form approaching the pinnate type of division, having a pair of sessile, deltoid, nearly bipinnate pinnae at the base, and six pairs of lateral, sessile, opposite, linear-lanceolate, deeply-lobed pinnae, gradually diminishing in size towards the pinnatifid point. The sporiferous panicles are much larger in this than in any of the others enumerated here; they resemble the green inflorescence of the Goose Foot (*Chenopodium*) in density. The variety *cheilanthoides* has a much more divided frond, with smaller roundish lobes, and its foliage, as well as that of the type, is of a bluish green, and tomentose, but this latter character is a variable one, as they sometimes occur nearly glabrous. It is chiefly confined to the West Indies and Brazil, but some of its varieties are found in the Tropics of the Eastern Hemisphere.

A. villosa.—This and the preceding are connected by a series of intermediate links, a circumstance which suggests the probability of their being extreme forms of one species, but they differ widely from each other as will be seen by the description. *A. tomentosa* has a short creeping rhizome, whereas the species in question forms an erect caudex, 4 in. to 6 in. in height, similar to a miniature Tree Fern; its foliage also is produced in much greater quantity, and is more hairy. Its fronds are simply pinnate, with a triangular-lanceolate outline, and from 10 in. to 12 in. in length, of a light bluish-green, and thickly covered with gray stiff hairs, which give the whole plant a hoary appearance. The lower pinnae are sometimes pinnatifid, but generally all the pinnae are only lobed, or crenate, and the branchlets of the panicle are very slender, and placed distantly from each other. The habit of the plant is very good, and deserves, with *A. mandioccana*, a place among the more select Ferns. It is a native of Tropical America.

A. aurita.—This is probably the only representative of the old genus *Coptophyllum* that has been brought into cultivation. Its barren fronds, which are triangular, are from 6 in. to 8 in. in length, including the stipe, with roundish serrated pinnules, which are prominently veined, bright green, and very coriaceous. The fertile fronds have no leafy segments attached, as in all the foregoing, but consist of an irregular branched panicle, with the final divisions similar to those of the true *Anemias*. It is indigenous to Jamaica.

C. M.

ORCHID CULTURE.

From their singular beauty, great diversity of character, and the ease with which they can be cultivated, Orchids, by this time, ought to have found a place in every garden however small. That this is not so is mainly attributable to the circumstance that, as a rule, they are grown in very high temperatures, especially certain sections of them; that this is not really necessary I have myself proved. Our *Vandas*, *Aerides*, *Saccolabiums*, and what are generally termed hot Orchids, when dependent on fire-heat, are rarely subject to a temperature above 60° during the growing season, and in winter they are for weeks not above 50°, and last winter they were as low as 45° in the morning. That they did not suffer from this treatment those who saw them at the late sale in Edinburgh can bear witness. Thirteen of our plants, none of them rare, realised £144; one *Vanda*, which Mr. Williams purchased for £30 10s., we had grown during ten years from a small sucker, and it never had lost a single leaf, the stem being clothed to the surface of the basket. This is rarely so with *Vandas* subject to high temperatures, especially from fire

heat. Allow me now to refer to a much more striking example of the success of moderate heat for Orchids, in the case of the fine collection grown by Dr. Patterson, of the Bridge of Allan. Nearly all the great Orchid growers in Britain have seen the doctor's plants, and those who have seen them recently, as I have, will readily admit that, considering the curious tumbledown sort of houses they inhabit, they are in marvellous health and vigour. His East Indian house is a sort of lounge for gentlemen who are temporarily resident at the Bridge of Allan, for the benefit of its healing waters, or for the good doctor's own skill as a physician. Here they may be seen sitting by the hour, burning their idols, and while there, as a spectator on the first of this month, a lady came in with the doctor; she was surprised at the gorgeousness of a fine plant of *Cattleya labiata*, the true variety in full bloom, and then said, "Why, doctor, I thought these plants could only be grown in hothouses, but this is a greenhouse;" the fact being that the door was standing wide open, and had been so from nine o'clock a.m. till three p.m. during the week I was at the Bridge of Allan. The weather, no doubt, was fine for the season. The fact that gentlemen sit with perfect comfort and smoke their cigars by the hour amongst East Indian Orchids, at all seasons of the year, needs no comment. I counted fifty-three plants in bloom; *Vanda cœrulea*, with sixteen flowers to a spike; I also counted seventy-one plants showing spikes. This, out of 550 plants, Orchid growers will readily admit to be a most satisfactory result of his management. With the aid of a woman, who washes and crocks pots and manages the fire, the whole potting and attention to the plants is the result of the doctor's spare hours from six o'clock in the morning till his patients claim his attention after breakfast. He is making an addition to his houses, which will enable him to give some of his gigantic Vandas, and other large plants, room to show themselves. No man I know of has done so much in his sphere to spread a taste for Orchid culture as Dr. Patterson; many are now as keen growers as he is, who got their keynote from him. He showed that they could be grown in a climate any one could stay in with comfort, while either tending or examining them, and that they can be grown with less trouble than any other class of plants; that they increase in value as they grow larger and older—a fact not true of most other plants, and that they have an interest which no other class of plants possess.

Tweed Vineyard.

WM. THOMSON.

ORCHID GROWING IN SHALLOW PANS.

WITHIN the last two or three years allusion has from time to time been made to the small pans in use for growing Orchids in Messrs. Veitch's nursery at Chelsea. The advantages that result from the use of these thin, light little pots are now so manifest that a few observations respecting them may be of service to those who have not had an opportunity of seeing them. The pans in question are made of well prepared material such as good garden pots consist of; their smallest size—speaking from memory—is about 2 in. or 2½ in. in diameter, and in shape they are not unlike the little trays used by smokers wherein to deposit cigar ashes, but a trifle deeper, and they are not much thicker than an ordinary tea saucer. The size just named is used for the smallest plants, such as newly-imported *Phalænopsis*; others proportionately larger are employed for plants of greater size, but all are made as light as is compatible with sufficient strength, and, as a matter of course, they are perforated in the bottom in order to allow superabundant water to escape. It thus will be seen that there is little or no depth for crocks or other drainage ordinarily used, nor is any needed, for the potting material employed is of such a character that the water can pass almost as freely through it as through a sieve.

Few greater mistakes can be committed in Orchid cultivation than over-potting, but by the use of these pans, even in the case of the most recently imported non-established plants there need be no fear of over-potting; and owing to their extreme lightness they can be hung up in quantities without their weight straining the roof. The plants can therefore be placed in the best possible position for free healthy growth, which in no way is more accelerated than through the greater disposition that exists for making roots when subjected to the direct influence of light close under the glass. I may here remark that all the different species grown in these pans thrive and attain a strength and vigour such as is not observable in the same species growing under conditions otherwise similar but in ordinary pots or baskets. The roots of Orchids will cling to almost anything with which they come in contact, but there is no material I have ever seen them adhere to that seems so favourable to their retaining lengthened vitality as earthenware such as garden pots are made of. The way the roots interlace and completely line the inner sides of these suspended pans, and long retain life, at once accounts for the plants thriving in them as they do

Another advantage is that, being so shallow, they allow of the whole of the potting material being picked out, when it becomes necessary to remove it, without disturbing the roots to any appreciable extent, the plants thus going on without the inevitable check that follows ordinary re-potting, until their size is such as to require larger pans. As I have already intimated one great thing in favour of the use of these very light pots is, that they admit of being hung up to the roof in quantity, with the roots in a great measure secure within the potting material, in a way not present where baskets or blocks are employed, which, permitting the roots to protrude, they are thus more liable to injury in various ways. It will be obvious that these pans are more suitable for some descriptions of Orchids than others; the thinner, denser-rooted kinds, especially such as *Dendrobiums*, *Phalænopsis*, in particular, do splendidly in them; there is one house at Chelsea almost wholly filled with the latter plants, some 6,000 in number, which is a sight worth going a long distance to see; the rate at which they increase in size—resulting from the favourable position they occupy—the security their roots are under, combined with judicious treatment, are such as require to be seen to be realised. Amongst *Dendrobiums* the difficult-to-manage *D. albanguineum* is in unusually fine condition; *D. Wardianum* and *D. crassinode*, some of the latter have pseudo-bulbs 2½ ft. long and proportionately thick, although the plants are in pans not more than 4 in. or 5 in. in diameter.

These Orchid pans, I believe, were an idea of Mr. Dominy's, who, as is well known to cultivators of these plants, has accomplished so much in the until recently untrodden field of raising Orchids from seed, and who is equally successful in their cultivation.

T. BAINES.

CYCLAMEN PERSICUM IN AUTUMN.

THE Persian Cyclamen is as much an autumn and winter flowering as it is a spring-flowering plant. This is a matter not so much understood as it needs to be, and we may go a step forward and state that generally the Cyclamen is not nearly so well grown in private establishments as it deserves to be, and as it ought to be. It was not an uncommon occurrence to meet with Cyclamen bulbs put out into the open air to roast in the sun, under the impression that they are being ripened. Then it was thought to be something akin to a floral feat to have the plants in bloom in March and April. Since then we have grown wiser as regards the management of the Cyclamen, and with this advantage that not only are the plants much more vigorously grown than they used to be, and the leaves more handsomely marked in consequence, but the flowers are much more numerous produced. With improved cultivation has come also marked advances in the size and substance of the flowers, in the production of brilliant colours, and in the richness and definiteness of their markings.

This year, owing to the lateness of the season, the Cyclamens are opening their flowers much sooner than usual. At Mr. H. B. Smith's nursery, at Ealing Dean, there is a very large collection of Cyclamens grown, especially of the large-flowering type, and many of these are finely in flower. Something like 10,000 plants are annually grown for market and other purposes, and they are arranged in the long, low, span-roofed houses peculiar to nurseries where plants are grown for market purposes; and when the plants are fully in bloom they present an almost unbroken surface of varied colours; an intermingling of charming shades of purple, pink, rose, carmine, &c., with dashes of white produced by the pure white varieties. The large-flowering section has become so popular that a preponderance of these is cultivated, and it is found they are as free bloomers as the smaller flowered types. The great majority of the plants are in what are termed 4½-in. pots; this is a size that seems to afford the plants every chance of fully developing themselves; it is also a convenient one for market purposes. The number of flowers found on one of these plants is something astounding, and it is this fact which makes the Cyclamen so valuable for picking from. It appears a rash statement to make, but it is not unusual for plants sixteen months from the seed pots to produce from 200 to 250 blooms each.

The Cyclamen flowers are not cut from the plants, but plucked off by taking firm hold of the stem a little below the bloom, and giving it a sharp snatch. It is easily and quickly separated from the corm, without injury to either, and at this time of year the flowers fetch a good price in the market. They will remain for a long time in water.

It is very interesting to note the manner of raising seedling Cyclamens on a large scale, and the thoroughly methodical character of the whole proceeding. The seed, which ripens in June and July, is sown as early in August as possible in pans of light, rich, sandy soil. These are plunged in bottom heat, and by the end of November the seedlings are pricked off into 3-in. pots, about fifteen plants in a pot, and kept in a warm, moist temperature. Here they remain till February, when they are re-potted singly into small, long thumb

pots, and still kept moving quickly in warmth. They are next potted into 3-in. pots, and about the middle of May they are finally shifted into their flowering pots, and as soon as established put out-of-doors into cold frames, where they are kept growing, being freely watered, sprinkled overhead, and shaded from the hot sun. A grower of some experience recommends cultivators of *Cyclamens* to proceed as follows: Sprinkle the plants early enough in the day for the leaves to dry before night, as if the lights of the frame in which the plants are be closed down while the leaves are wet, the foliage is apt to become drawn. In the case of seedling plants there is no resting space, nor does the plant require any. The earliest and strongest plants, if kept growing on and well looked after, will bloom in October. Mr. Smith in ordinary seasons has many plants in flower by the time autumn might be said to commence.

Mr. Henry Little once showed me some plants in his collection that had bloomed five and six years in succession, and wonderful specimens they were; but they would not have become these had they not been carefully looked after. After the first year of flowering, the bulbs kept over to flower again the following season need some period of repose, but that is a very different thing from neglecting them. They are placed in a cold frame in a sunny aspect and kept moderately dry, but nothing like so dry as our forefathers kept them; and when they begin to show signs of growth they are repotted, put into a frame, kept close at first, and then grown up generously into fine plants. These do not, as a rule, flower so early as seedlings, but they are had in bloom much earlier than is generally supposed.

The best soil for the *Cyclamen* is one made up of light loam, leaf-mould, and a little sand. If it is what is known as a clinging loam, it is well to mix a little peat with it to keep it open. The pots must be well drained; a soddened soil is very hurtful to the *Cyclamen*, and it is very important to be guarded against.

R. D.

GESNERAS AND THEIR CULTURE.

AMONGST plants that are especially adapted for autumn and winter decoration the *Gesnera* still holds a foremost place, combining as it does the properties of both a fine foliaged and flowering plant in a striking degree. Its leaf markings are exceptionally rich and varied, and the flower spikes, when well thrown up above the foliage, form collectively a perfect ideal of a vase or table plant. We have lately been using *Gesneras* somewhat extensively for indoor decoration, as in addition to their suitability for single vases, they give a rich look to groups or large mixed stands of plants, and withstand the ordeal of subdued light and the usually dry atmosphere of ordinary living rooms better than most plants. *G. zebrina* and *zebriga splendens* are beautifully striped, or rather veined, with dark colours, on a rich green ground. *G. cinnabarina* is also a very excellent variety, dwarf and sturdy in habit, and as its name implies bronze or cinnamon in colour.

As regards culture we usually shake the old bulbs or roots out in April, and start them in boxes or pans in light sandy soil, placing them in a Cucumber house or Vinery where a brisk heat is maintained. As soon as they are fairly started into leaf growth, they are potted at once into the pots in which they are intended to flower. We find single plants in 4-in. or 5-in. pots the most useful for vases or for mixing in groups; but if large specimen pots are required from three to six plants may be used with good effect. The compost which we use is turfy loam, peat, and leaf soil, or thoroughly rotten cow or sheep manure, and plenty of sharp silver sand. The pots should be well drained with dry clean potsherds, for although *Gesneras* delight in plenty of root and atmospheric moisture, anything like stagnant water at the root, or a stoppage of the drainage, will prove fatal to them, and if once during the growing season their leaves flag, they seldom recover. They should be shaded from strong sunlight, as they are very easily scorched. We have grown the majority of our plants in the Cucumber house, which was shaded on the south side, but not on the north, and the temperature and general treatment to which the Cucumbers were subjected suit the *Gesneras* admirably, as without a good command of heat and moisture neither will be satisfactory.

Under favourable conditions *Gesneras* are not liable to insect pests, but should mealy bug get established on them it must be carefully removed, as rough usage would be fatal to their leaf beauty. They well repay all the attention that may be given them, and if not required for indoor decoration they prove a source of great attraction in the stove during the duller and most flowerless months of the year. When their beauty begins to fade, moisture should be gradually withheld; but as long as the foliage remains intact they should be exposed to the light, as on its functions being properly performed to the last depends the size and vigour of the tubers for next year's work. After the foliage is decayed they may

be stored under the stage of the stove, where, if the pots are laid on their side, the soil will keep in a condition to retain the vitality of the roots in the best condition for starting again in spring.

J. GROOM.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Double Violets.—It will not be difficult to have plants of these early in bloom this season, as the cool condition of the summer has been specially suited to the production of robust-blooming crowns. Plants needed for winter-flowering should be lifted from the open ground at once and be potted, the best for this purpose being close, compact clumps that will furnish plenty of bloom from a small space. Side shoots put in last autumn that have had the benefit of rich soil should now present good potting clumps. The new white, or as it is in the open air, rosy-white, *Belle de Chate-nay*, has a robust habit, and will make a favourite kind either for open beds or for frames. Though not so pure as the old double white kind, it blooms more freely, and is not so loose in its growth. *De Parme*, another new kind, comes so near to the old *Marie Louise* that it is either that kind or a near relation to it. Still, it is a fine kind, and a great advance upon the Neapolitan; the flowers are larger and rather deeper-coloured, and more freely produced. The old double blue has, perhaps, the fullest and neatest flowers of all the kinds, but the stems are short. It is, however, very beautiful when grown in frames or in beds in the open ground, where the thick growth keeps the flowers well up from the soil. *Blandyana* is of a better habit and a somewhat freer bloomer; the flowers are rather larger, but not quite so dark or so neatly formed. The Neapolitan will doubtless ever be a favourite, in spite of other and newer kinds, but it is not quite so hardy, and needs a frame to protect it in severe weather. A number of plants of each of these kinds in pots will supply Violets for gathering all through the winter. A gentle heat furnished by a mixture of leaves and manure will start some early, and the rest will bloom much earlier under glass without heat than naturally in the open ground. For button-holes or for the perfuming of a room Violets are ever welcome.—A. D.

Lilium auratum.—A bulb of this Lily, which I got last year, and which had come, I believe, from Japan, flowered in this fashion: There were sixteen flowers, of large size, in two absolutely symmetrical rows, one close above the other, and forming a perfect crown. The lower row came out all at once, about a couple of days before the upper row, which, after expanding, projected slightly beyond the lower. After both tiers were fully out, the crown stood complete for about ten days. The lower row then fell. The colour was good, and altogether it was a wonderfully beautiful object. I never happened to see this Lily flower in this way before, and it may be a mere sport. The stem is perfectly round, but there is a tendency to coalescence in a few of the leaves. I shall look out with interest for the behaviour of this bulb next year.—C. WYVILLE THOMSON, *Bonsyde, Linlithgow*.

Pteris serrulata cristata.—This large-crested variety of one of the oldest and commonest of hothouse Ferns is admirable as a decorative plant when grown into bold specimens, the outline of the plants being broken and varied and the tasseled shoots elegant. There are great numbers of this Fern grown at Chiswick for South Kensington. It would be also good for room decoration.

Bulbophyllum Beccari.—As regards foliage this is the most remarkable Orchid that has been introduced for many years, the leaves being more like Zulu shields than the foliage to which we are accustomed in an Orchid. They are frequently 18 in. long and 1 ft. wide, stiff and firm in substance. Mr. Bull has quite a quantity of this Orchid, and it will be interesting to see what kind of flower it produces.

Chamædorea glaucifolia.—This is a poem of grace, if such a thing can be said of any plant. I have noted of late years many graceful Palms, some of which are happily becoming more common in our houses, and will one day tend to make them more graceful and verdant; but I think, for bewitching elegance of form, this is second to no other. There are good specimens of it in the Aroid house at Kew.—V.

Cocos Weddeliana.—This most exquisitely graceful Palm is likely to be an ornament of every hothouse some day, as it has recently been raised in large quantities. House s of it in Mr. Bull's nursery look like fresh meadows, owing to the grace and the verdure of the elegant foliage.

Sarracenia flava ornata.—This is a distinct and handsome Pitcher Plant, remarkable for its bold and strongly pronounced venation. The upper part of the pitcher is of a dark purplish-red, which is continued over the lid. It is a very handsome form, the contrast between its clear green and the bold red venation being striking and very effective.

Selaginella Kraussiana aurea.—This is a golden tinted variety of the common *Selaginella* of our hothouse, having the same free-growing habit as the type, and differs from it only in the colour of its leaves, which, instead of being green, are yellowish. The plant will be valuable for similar purposes to those for which the very popular old plant is used.

Culture of Bouvardias (p. 415).—"J. S. W.'s" mode of growing these is simply the old slow system that I and others who have long known and grown them tried, and found so far wanting as to give it up for a better. "J. S. W." incidentally divulges what his estimation of well-grown Bouvardias is when he instances the plants sold at Covent Garden Market, which are about half the size and strength that plants grown in the way I advise will attain in the time, and are not capable of producing more than half the blooms that they should do during the autumn and winter, which is the season I had in view when writing on this subject. By the method which I recommend for growing and blooming Bouvardias, double the quantity of flowers can be produced in the same time, and of better quality, than by the old or cool system.—T. BAINES.

Ficus Parcelli.—This is a very distinct variegated plant, and one that is useful for decorative purposes. I find that it requires confining to a small root space in order to get the variegation clear and well developed. When the white portion predominates, and the green is clear and well defined, it forms a very effective subject either for a vase singly, or for mixing in groups.—J. GROOM.

Christmas Roses in Pots.—No one, I suppose, ever has too many Christmas Roses, any more than they do of the still more beautiful Roses that are the delight of all in summer and autumn; but those who have not grown the former in pots do not know how very manageable they are under cold pit or greenhouse treatment. Their thick, leathery leaves and strong, fleshy roots, of course, furnish evidence that they can bear hardships, but they do not like a very warm house, but in a cool greenhouse strong plants continue to produce flowers for a long time. They may be potted up from the beds now, but the best time to do this is early in the season, plunging the pots afterwards in the open air, and keeping them well supplied with water. Rather strong loam, with about a fourth part of manure well incorporated with it, suits them best, using pots rather large in proportion to the size of the roots, as it is not necessary in all cases to repot every year. I have a number of plants of *H. niger* that have occupied the same pots three years, still increasing in size and in number of flowers borne; but any plants that seem pot-bound should be repotted in spring, or, if they already occupy large pots, divide the roots into two or more plants, and pot separately. If a large stock is required, one old plant may be cut into a dozen, or perhaps more, and be planted out in a nursery bed for a couple of years. Each piece may be cut off with a bud or crown and a root or two that will soon establish itself. The spring is the best time for division.—E. H.

Potting and Planting Bulbs.—In the remarks on this subject by "S. D." (p. 389) it is stated that double Tulips such as *Tournesol*, *Rex Rubrorum*, *Duc Van Thol*, and *Marriage de ma Fille* "are more showy than single kinds," a statement to which I am sure many will take exception. *Tournesol* is undoubtedly the prince of double Tulips; *Rex Rubrorum* is disfigured by the green petals mingling with the coloured ones; *Duc Van Thol* is quite unworthy of cultivation in pots; and *Marriage de ma Fille* is too tall in growth and far too late in flowering to be of much value for pot culture. The single varieties of the early Tulip are much to be preferred for pot culture to the double ones; they have larger and richer coloured flowers, they are generally dwarf in growth, and fine in form. In all competitions with early Tulips it will be invariably found that the single varieties are grown for the purpose, while in beds they have a far greater decorative effect. The following is a list of a few varieties which I can heartily recommend to those who may be thinking of growing a few in pots: *Scarlet* and *crimson self*—*Scarlet Van Thol*, *Purple Crown*, and *Vermilion Brilliant*; *white self*—*White Pottebakker*; *yellow self*—*Canary Bird* and *Yellow Prince*; *violet* and *purple self*—*Molière*, *Proserpine*, *Queen of Violets*, *Van der Neer*, and *Wouverman*; *striped*—*Comte de Vergeunes*, *Fabiola*, *Joost Van Vondel* (rich rosy-erimson with broad flakes of white, sometimes self rosy-erimson), *Roi Pepin*, *Queen Victoria* (white, flamed with rose), and *Royal Standard* (scarlet and white); *tipped flowers*—*Kaizer Kroon* (one of the very finest of early Tulips, shaded scarlet, heavily tipped with gold), *Duchesse de Parma* (erimson and gold), and *Couleur Cardinal* (erimson, feathered with vermilion). I have known early single Tulips kept for a long time in flower by simply tying round the blooms when they have attained their full size a piece of silk thread as near as possible answering to the colour of each, and the pots kept in a cool, shaded house. In potting, three bulbs of one variety should be put into a 4½-in. pot, and treated in the same manner as *Hyacinths*.—R. D.

THE GARDEN FLORA.

PLATE CCVI.—HÆMANTHUS KALBREYERI.

Drawn by MISS DUFFIELD.

THE subject of our plate this week is one of the "Blood Lilies," and rich though they are in kinds possessing brilliancy and beauty, this is one of the finest of them. To Messrs. Veitch belongs the credit of its introduction, but to Mr. Bull we are indebted for the specimen from which our plate was prepared. It was discovered by Mr. Kalbreyer when collecting for his firm in Guinea, and is localised as from the Isles de Los, where it was found growing in open spaces under trees. It comes between the new *H. Manni* (*Bot. Mag.*, t. 6364), and the old *H. multiflorus* grown in gardens for the last 250 years. It is a species with a rootstock rather than a bulb, from which proceed fleshy cylindrical fibres. The leaf-stem is developed after the flowers. It is about 6 in. long with copious elaret blotches on the green ground, and bears two or three oblong leaves from 9 in. to 10 in. long, and about 3 in. broad, bright green on both sides. The flower-stem is lateral, reaching, according to Mr. Kalbreyer, a length of from 2 ft. to 3 ft. The floral cluster is from thirty to forty-flowered, and measures from 5 in. to 6 in. across. The bracts or leaves which enclose the flowers are small and turn down, not, as in some kinds, the chief attraction of the plant, as, for example, in the case of the Cape Tulip (*H. coccineus*). The segments of the flower are narrow, and spread 2 in. across. The yellow anthers are supported on red filaments 1 in. long. Description fails to convey an adequate conception of the beauty of this *Hæmanthus*, but the accompanying plate will give a good idea of its worth. We can only hope that other fine species may be led by it into fashion. The genus *Hæmanthus* may be divided into two groups, the first being characterised by large, thin, undulating leaves, sheathing together and forming a false stem, as seen in the *Banana* and *Crinum*, from which the flower-stem is either lateral, or comes up in the centre. The bulb of this group, too, is distinct in formation; it has always a large development of the stem portion, and the scales or coats are often so far absent as to leave a mere root-stock. To this belongs *H. multiflorus*, and the present species in the division with a spreading flower, and *H. puniceus* and *H. natalensis* in the division with the floral segments erect. There are other species, but these suffice for instances. *H. Manni* and *H. Katherineæ* are new kinds in cultivation, and allies of the plant now under notice. In the other group the bulbs are compressed, the leaves are opposite, succulent, do not sheath, and are not undulating. It is divided in the same way as the last. Amongst kinds with spreading flowers are *H. carneus*, sometimes called *roseus*, and *H. lanceifolius*. Amongst those with erect flowers are several species, of which *H. hirsutus*, *H. albo-maculatus*, *H. Arnotti*, and *H. deformis* are new, or comparatively so; there is, moreover, that grand old plant, *H. coccineus*. *H. moschatus* is remarkable for its scented flowers in an otherwise scentless genus. *H. albo-maculatus* is known from all others by its spotted leaves, which are to it a special ornament.

There are about thirty-five species of *Hæmanthus*, of which, perhaps, twenty are in cultivation. One hybrid we know of, viz., *H. albiflos* + *H. carinatus*, raised by Colonel Clarke. *H. Rouperi* we should like to see more of, as it is evidently a fine kind. It is allied to *H. insignis* and *H. puniceus*, from both of which it seems to differ. It is cultivated by Messrs. Henderson & Son, and appears to be distinct, though it has not been, I believe, described or examined by botanical authority. A very interesting plant, *Buphane toxicaria*, has been referred to the Blood Lilies, but wrongly so. It is the Poison Bulb of South Africa, the viscid juice of which is used by the natives for poisoning their arrows.

The culture of the *Hæmanthuses* is by no means difficult; whether they are in a suitable house or not, however, makes a considerable difference. The kind of structure most suitable for bulbs of this character is that of a lean-to or half-span, with the back-wall facing the south, and so managed within as not to be permanently moist. There may be two borders of spar or gravel, one in front for the smaller plants, another at the back for larger specimens, and between the borders should run a pathway. A portion of each border might be prepared with soil and stones in which to plant out, a method calculated to produce the finest results, but with the drawback that flowering specimens could not be conveniently moved. No doubt a span-roofed house, with a path all round, would answer well, especially for a general bulb collection, where some would need a certain amount of shade. We have in view houses of both classes, and another very excellent system of culture—that once pursued at Hillfield, under the late Mr. Wilson Saunders, where Mr. Green was gardener. There in front of some of the houses were low glass frames covering a prepared border, in which all sorts of choice subjects were planted. Sufficient heat came from the structure against which the frames leaned, and

the ventilators could be made to open into these miniature glass ranges. In summer when the natural heat is sufficient, the lights were removed, and the plants had the full benefit of exposure to sun and air. Some species would do well in such frames, but for the more northern species, as in the present instance, we should prefer a house, having found them do well even in nearly a stove temperature. The soil to be preferred is a rich friable loam, without, if possible, any admixture. In our opinion natural soils when of suitable character are always better than mixtures, not only for these but many other subjects. Manure as a rule is not desirable. It is better to assist with liquid manure at the right season, it being without the objection that belongs to manure and leaf-mould, viz., losing bulk and otherwise affecting the soil at a time when it is too soon for repotting. These fleshy-rooted plants are better if allowed to remain in an established condition for a considerable period. Pot them in moderately small pots, and observe how well some kinds thrive, sometimes even bursting the pots. *Hemanthus Kalbreyeri*, like its near allies, flowers in summer; therefore, as this season approaches, carefully administer water, and, as the heads show, gradually increase the supply. With full exposure to light, water may be given freely during growth, afterwards withholding it as the plants go to rest; then after proper ripening an only occasional watering will suffice during the winter. At this season a temperature of 40° to 45° F. will be found to answer. Observe that the plants are not unnaturally dried by too high a temperature of the pipes, or in too close proximity to them. L.

GARDENING FOR THE WEEK.

Flower Garden.

PRESUMING that the flower beds have been filled, either with material for winter effect, or with spring-flowering plants and bulbs, there will now be little else to do in the flower garden proper, except the maintenance of neatness, which is a matter more than ever desirable at this dulllest of all seasons of the year. In other portions of ornamental grounds, which are generally designated flower gardens, there may still be found abundant work, such as thinning out clumps of shrubs, or planting additional ones or single specimens, of either deciduous trees or evergreens. Any tree or shrub may at this season be moved with safety. Of late years there has been such a demand for Coniferous plants, and particularly within the last two or three years, for the Japanese kinds, that deciduous trees have become neglected; and, granted that this class of plants is interesting and beautiful, still, at the present rate of planting them, combined with a proportionate neglect of deciduous trees, ornamental grounds a few years hence will present more the appearance of cemeteries than that of pleasure grounds. To prevent this in all new planting there should be a judicious admixture of the finer deciduous trees, such as *Acacias*, *Maples*, *Thorns*, *Turkey Oaks*, *Tulip trees*, *Liquidambar*, *Purple Beeches*, *Lombardy Poplars*, *Spanish* and *Horse Chestnuts*, &c. In forming clumps of shrubs also, evergreens are often too prominent, whilst flowering deciduous shrubs, such as *Lilacs*, *Deutzias*, *Snow-berries*, *Spiræas*, and *Weigelas*, which are, in every way, suited for association with the dwarfier-growing evergreens, are neglected. Half-hardy plants that are to winter in the open air should now receive partial protection by surrounding the base of the plants with ashes, *Cocœa-fibre*, or bracken, and some of the choicer Ferns and rock plants will require the same attention. *Dahlias*, *Gladioli*, *Tigridias*, and *Marvel of Peru* should all now be dug up and dried previous to finally storing them away. The ground is so full of moisture that it will scarcely be safe to leave *Cannas* out for the winter. At this place last season all were killed, though well protected with bracken, so that my impression is that a sodden state of the ground is more fatal to them than severe frost. If lifted the roots will winter safely in any place from which frost can be excluded. This is the most critical time for the well-being of bedding plants; damp is their great foe, and therefore water but sparingly, and keep the hardier kinds well exposed to induce sturdiness. Tender kinds, such as *Coleuses* and *Alternantheras* will not winter successfully in a lower temperature than 65°, and they must be kept well up to the light.—W. W.

Auriculas.—Remove from beds of Alpine *Auriculas* out-of-doors all decaying leaves, and destroy weeds before they grow to a large size. The surface of the beds should be loosened either with a small hoe or a pointed stick. Slugs are very fond of the leaves, and perhaps the best way in which to destroy them is to pick them off at night. If previous instructions have been observed as to planting and making the beds these will be a little higher than the surrounding surface; a damp, close soil, as low as the neighbouring

surface, does not at all suit these Alpine sorts. For out-of-doors culture seedlings are better adapted than choice named sorts. A packet of seeds costing about half-a-crown would produce as many plants as would plant a large bed. It is not the time to give precise instructions as to sowing the seeds, as March is a good month for that operation; they are, however, easily raised, and the plants can be grown on to a flowering size with but little expense or trouble. I have seen plants of Alpine and show *Auriculas* thriving remarkably well on a sheltered bank in the garden at Stakehill, near Manchester, a miserably smoky locality. They were planted amongst lumps of stone or clinkers, and in such a position that it was not possible that water could lodge about the collars of the plants. However much these fine plants may be valued for frame culture, it is even more desirable that they should be introduced into the flower garden wherever practicable as hardy occupants of that department.

Carnations and Picotees.—The ground is at present in very favourable condition for planting out in beds, and if a sufficient number of plants can be obtained, planting ought now to be proceeded with. Near London we do not think of planting choice varieties of *Carnations* and *Picotees* out-of-doors to stand over the winter, and yet so far north as *Newcastle-upon-Tyne* this is done successfully; growers there will now be making arrangements to plant. The flowers exhibited annually at *Newcastle* from plants grown in the open air are wonderful examples of skilful management. If the plants are put out in the spring such good flowers are not obtained. When the plants are put out a small stick is placed to each, in order to prevent the wind from snapping them over, and the surface of the beds has to be covered with some dry, rotten, stable manure. This mulching prevents the plants from being thrown out of the ground by frost, and also further helps to steady them. Damp is one of the worst enemies with which the *Carnation* has to contend; even intense frost is not injurious.

Hollyhocks.—If the choice varieties have not yet been taken up, this ought to be done at once, and no time should be lost in potting them. The roots should be cut back considerably, and all old leaves removed, in order to allow the young growths at the base of the stems to develop themselves. Do not over-pot, nor squeeze the roots into a pot not quite large enough to contain them, although that is better than over-potting. See that the young plants are kept free from red spider and other pests. If the plants have been put out in a cold frame, the leaves will continue to decay in damp foggy weather; let them be removed at once to prevent further injury. Some take off the cuttings from the base of the stem now, but I would only recommend this to be done if there be so many that they would injure each other during the winter. January, February, and March are the best months in which to propagate for late flowering plants. See that the frames are freely aired, removing the lights as often as possible with safety.

Pansies and Pinks in Beds.—The fine autumn weather which we have had has been exceedingly favourable to the growth of young plants of both of these put out in beds; see, therefore, that they are kept in good condition. Any plants that seem as if they would not form free-flowering healthy specimens should be removed, and others taken from the reserve stock to fill up their places. It is necessary that this should be done in the case of scarce sorts that are weakly. They should be taken out and be repotted in small pots or they may be lost altogether. Pinks may be treated in the same way. A pair of plants should be wintered in a 3-in. pot, and treated in the same manner as *Carnations* and *Picotees*. If there are any vacancies in the beds of Pinks they must also be filled up from the reserve stock in pots kept for this purpose.

Forcing Pinks.—These are now, or ought to be, well-established in their pots. Go carefully over the plants and remove all dead and decaying leaves. Stir the surface of the soil, and press down the plants gently by placing the fingers near the stems. Give plenty of air at night as well as by day, unless there is danger of frost.

Polyanthuses.—These we winter in a frame with Alpine *Auriculas*, as they require very similar treatment in regard to ventilation and watering. We would not like to see show *Auriculas* get a drop of rain, but a gentle shower would not hurt the others, which require rather more water at the roots than *Auriculas*. It does not do to let them get quite dry, but that would not in the least injure *Auriculas*. Even now red spider holds its own on some plants that were sent here late in the autumn, and this after recent drenchings with soapy water.—J. DOUGLAS.

Stove.

Winter Blooming Stove Plants.—It is a good plan at this time to look over the stock of these which are to afford the principal supply of flowers for the next three months, with a view to keep up a succession so as not to have more in bloom at any time

during the period than requisite, with a corresponding deficiency at others. Such portion of the stove plants usually propagated each year for winter flowering as it is deemed necessary to treat so as to come later into bloom than those that receive heat enough to bring them on at once, need to be cautiously managed betwixt this and the end of the year, when the temperature, especially in the nights, falls low; whilst what may be termed a slightly retarding process is being carried out with them, otherwise they are apt to get chilled, the effect of which would be to very much interfere with their blooming capabilities at the time they are required. This applies to the winter flowering Begonias, Plumbago rosea, Euphorbia jacquiniiflora, Poinsettias, Eranthemums, Moyaenias, Thyrsacanthuses, Pentas carnea, Gesneras, and others of similar character. Such portions of any of these as are now in flower should, so far as possible, be kept where there is no more heat than requisite to preserve them in a healthy condition, as ever so little more warmth than needful tends to shorten the duration of the bloom. Those that are coming on ought to be treated similarly, so far as the time when they are wanted in flower will admit of. In all cases I should advise no more water being used at the roots than absolutely requisite with any plants now in a somewhat lower temperature than they enjoy. This is particularly necessary for those that are not very free rooters; the atmosphere also, wherever stove or intermediate house plants are located, should be kept correspondingly drier, as when there is more humidity in the air of the house than needful to support the much reduced evaporation from the leaves, it directly tends to cause the flowers to be softer and less enduring.

Alamandas.—Where plants of these exist grown on the roof, either planted out or in pots, the time of putting them to rest will be dependant upon the purpose they are required for; if not needed in bloom until late in the spring they may still be kept on blooming, and at no season will their flowers be more useful than for some time yet, as when not exposed to an unusually cool dry atmosphere, I have found them last longer in a cut state through the winter than during the spring and summer; and where the house in which they are grown affords heat enough to keep them flowering up to the end of the year, and even beyond this, all that is necessary is to give as much water to the roots as required; but where they are wanted to bloom early, and consequently to be cut back about the beginning of the year, it will be better to now subject them to a drying process at the roots that will stop all further growth.

Æschynanthuses.—Where these are grown hung up in baskets and pots in the way they are seen to the best advantage, the soil should be kept as dry as can be done without causing their leaves to shrivel, which will permit of the shoots being now shortened back so far as deemed needful previous to their again commencing growth. The advantage gained by so treating these plants and others of like character that are hung up from the roof is that by the reduction in their heads they intercept less light from the main occupants of the house.

Hoyas.—The drooping kinds, such as *H. bella* and *H. Paxtoni*, so useful for suspending like the *Æschynanthus*, if their shoots are not well shortened back each year, get into a long, straggling condition, and cutting them in now, as advised with the last-named plants, will answer equally well to deferring it until spring, providing corresponding care is taken to give them no more water than requisite; and when their heads are thus reduced there is a better chance of clearing them from scale, bugs, or any similar insects with which they may be affected.

Dichorisandras.—The handsome and distinct *D. masaica* and other useful kinds, such as *D. vittata*, will now, where grown moderately warm, have done flowering, and should be stood where they will for a time be at rest, but not kept so cool as to injure their roots. To check any disposition to grow for some time it will be advisable to give no more water than just enough to keep the soil slightly moist. These, like other stove plants whose natural season of flowering is in the autumn, are the most serviceable when treated so as to induce their blooming late when flowers are scarce, and I have found that unless they receive a tolerably lengthened rest through the winter there is a disposition to bloom too early.

Gardenias.—Plants of these required for flowering now, for some time forward should have the best position that the warmest end of the stove can afford. They are, more than many things, liable to drop their bloom-buds in the winter season, often when so far advanced as to be almost on the verge of expanding; extremes from any cause, either of being too dry or too wet at the roots, too much moisture in the atmosphere, too much heat suddenly applied, or the opposite of being too cold, especially after the flowers have attained considerable size, will cause their falling off, although the mischief will not always be apparent for some weeks after, whatever may bring it about has occurred. The most effectual means I have ever found for avoiding the flowers dropping is to keep the plants in a

light position as possible. The little *G. citriodora*, blooming as it does in such a small state, if grown in quantity will always be found useful, especially where many flowers are wanted for bouquets.

Amaryllises that bloomed late, and made correspondingly late growth, will, like the earlier portion, now need keeping at rest. This refers both to the deciduous and evergreen kinds; the former are safe anywhere with the heat of an ordinary greenhouse, and will bear the soil keeping quite dry. The evergreen sorts need to be somewhat differently managed, and although plants that are very easy to grow, they are often by those who have not had much experience with them not so well done as those that are deciduous, for, unless in the case of such as are naturally the freest flowerers, if they are not kept sufficiently dry during the winter they appear never to get fairly to rest; but, on the other hand, they must not be let to become so dry as to cause their leaves to shrivel, as where this happens some premature loss of foliage is sure to occur, which at once reduces the strength of the bulbs; and it frequently happens that this pinching process is carried out with plants that have not attained enough strength to bloom; in this case they are only weakened for no purpose. With young stock of the evergreen species I should not advise the roots being further dried than will result from keeping the soil in a slightly moist condition.

Tuberoses.—There are few things that afford such a long succession of flowers as Tuberoses, for where enough are grown they may be had in bloom for much the greater portion of the year. Their delicious fragrance and lasting abilities when cut render them, where white flowers are needed, quite equal to *Stephanotis*, and if the management is fairly understood, a long continuance of bloom may be kept up much easier than with *Stephanotis*. I should advise those who want to have them in good time, to at once provide a sufficient quantity of roots, potting a portion up without delay, and keeping the remainder dry for the present, potting them at intervals. The American-grown roots are held in much the most favour at the present day. Those who have had little experience with these plants often fail in getting the bulbs to start, generally through their decaying instead of forming roots, and to which they are very liable unless great caution is used in the matter of water; for if the soil is kept in anything approaching the moist condition that most other plants would need the mischief is almost certain to occur. I have succeeded best by potting them in soil in a comparatively dry state, and then standing the pots on the earthen floor of a pit, or some moisture-holding material slightly damp, from which the pots will usually absorb enough until the roots are well in motion, when they will bear the soil to be kept fairly moist.

Deciduous Stove Plants.—All the remaining stock of these that are usually dried off through the winter, including *Gloriosas*, summer-flowering *Gesneras*, *Gloxinias*, *Achimenes*, *Caladiums*, &c., will now require to be put to rest, but avoid the common error of keeping them too cold, or placing them, as is often done, under stages near pipes that are sometimes too hot and at other times the opposite. In such places the soil frequently gets wet with the water that runs from plants on the stages above, and, if severe weather comes, necessitating the use of considerable fire-heat, the roots get too much dried up. Whilst at rest, the temperature of an intermediate house will suit them best, but where room in this way cannot be afforded, so as to allow their remaining in the pots in which they have been grown, let them be taken out and put in dry sand in boxes or paper bags.—T. BAINES.

Hardy Fruit.

The weather has been a source of annoyance for some months past, but at length a desirable change has come, for there could not possibly be a more favourable season than the present one is proving for garden operations of every kind, and more especially for fruit tree planting, which is always best done as early in the autumn as circumstances permit. The necessity for early planting and renovation of fruit tree borders has been so often insisted on in these pages, that nothing further need be added except that such work should, if possible, be brought to a close by the end of this month. Any that then remain to be done had better be deferred till vegetation again becomes active. Though these notes are only intended as hints and reminders of work to be done, as obviously—even if desirable—cultural details would take up too much space, yet a few words to beginners and the inexperienced in planting may perhaps be of service. From the foregoing it will be seen that we attach some importance to the season, or what may be termed the right time for planting; but after all, comparatively speaking, this is but a secondary consideration, as successful planting may be done any time from October to April; but we attach the greatest importance to the mode of planting; by which is meant not only the literal planting of the trees, but the proper preparation of the ground for them, and in doing this the first essential is good drainage. Every kind of cultivated hardy fruit, from a Peach to a Gooseberry, resents anything

like a stagnant state of the soil; moreover, good drainage increases by several degrees its temperature, and, as a matter of course, this must aid the more perfect development of the fruit, particularly in such a season as the one we have just passed through. The kind of soil that suits fruit trees generally is a calcareous loam of moderate texture—that is, neither heavy nor light—but of necessity this matter must be subject to local considerations, as often the soil best suited for certain trees is not obtainable; but, though there is a best kind, they are by no means fastidious, and all soils worthy of the name can by a little outlay of time and money be made to grow fruit well. Light ground should be trenched very deeply, and, if procurable, heavy loam or clay should be intermixed with it, but if this be not obtainable, well firming will in some measure atone for its absence. The opposite conditions, that is, very heavy or clayey soils, should also be trenched, and any sort of material that would render it more porous, such as mortar rubble, charcoal, and cinder ashes should be added, and it must be allowed to subside naturally, without artificial compression. Unless the soil be very poor indeed, no manure of any kind should be mixed directly with it, for the simple reason that the disposition of all fruit trees, when planted in rich soils, inclines towards the production of wood rather than fruit. It must not be inferred from this that manure is not essential to the production of good fruit, for it most certainly is, but never till the trees have fairly begun fruiting, and then annual surface dressings have the most marked effect, for, thus applied, it is not only valuable from a fertilising point of view, but it tends to keep the roots near the surface, a position in which they are most benefited by the action of sun and air. Yet how often do we disregard this question of surface-rooting, and, as it were, drive the roots downwards by digging and cropping the ground which they occupy with vegetables, &c. The whole question resolves itself into one of space; all who have plenty of ground for kitchen garden crops should never think of encroaching on the fruit tree borders, and those who by the force of circumstances must thus crop, should at least allow each tree a fair modicum of space. Keep the roots near the surface; deep planting is an error which some make through the erroneous impression that unless so buried they will be injured by frost. Above all, let them be well spread out, and the soil worked well amongst them with the hand, and afterwards let the trees be securely staked, for till that is done all fresh roots that may be made will, by the first gale, be destroyed through the swaying to and fro of the tree.—W. W.

Extracts from my Diary.—November 17 to 22.

FLOWERS.—Sponging Crotons, Dracenas, and Poinsettias. Staking *Adiantum Farleyense*. Getting up Dahlias, and placing them in boxes for the winter. Gathering seeds of Brier to produce stocks for Roses. Boxing *Echeverias*. Potting *Centauria ragusina*, Stag's-horn *Pelargonium*, and Lily of the Valley for forcing. Getting a few more *Primulas* and *Cinerarias* into heat for blooming. Taking up from outside border East Lothian Stocks, potting, and placing them in cold houses. Placing a few more *Spiræas* in heat. Sowing *Cyclamen persicum* in boxes and pans. Staking *Mignonette*. Tying *Azalea* and *Eupatoriums*.

FRUIT.—Looking over *Trebbiano* Vines and cutting out laterals and decaying leaves. Tying Vine shoots in early house. Keeping early Peach house close preparatory to starting. Looking over Apples and Pears in fruit room. Cutting Melons, wrapping them in cotton wool, and placing them on pipes in Melon house to ripen. Looking over Pines, and watering all requiring it. Digging holes for planting fruit trees. Taking the surface soil off early Peach house border about 2 in. in depth.

VEGETABLES.—Putting *Seakale* into pots, and placing it in a frame for forcing. Tying and thinning Tomatoes and winter Cucumbers. Potting Osborn's French Bean. Cutting all Self-protecting Broccoli ready for use. Spawning Mushroom bed outside, and turning manure for other beds, mixing it with a little earth. Digging ground for spring cropping. Looking over Tomatoes in Vinery, and picking out those decaying. Covering up *Seakale* bed outside with manure and leaves for forcing.—R. G., *Burghley*.

Hardy Florists' Flowers.—Under this title Mr. James Douglas has a work in hand which will be published shortly. It will contain an introduction by the Rev. F. D. Horner; chapters on the propagation, cultivation, and raising of new varieties of *Auriculas*, *Carnations* and *Picotees*, *Tulips*, *Polyanthuses*, *Chrysanthemums*, *Dahlias*, *Gladioli*, *Hollyhocks*, *Ranunculuses*, *Pinks*, *Pansies*, *Phloxes*, *Antirrhinums*, and *Aquilegas*, with select lists of each class. It is also to contain a monthly calendar of operations; and numerous illustrations, amongst which is to be a portrait of Mr. Charles Turner, from a photograph by Elliott & Fry.

THE PHYLLOXERA IN FRANCE.

ONE must have been at Bordeaux and heard that word "Phylloxera" uttered by a Bordelais to realise all the irritation associated with it. When a Bordelais speaks of the Phylloxera an idea can be formed of the way in which of old Montagues and Capulets spoke of each other, with such hatred, such terror, such thirst for vengeance does he pronounce the word. Looking at the suffering Vines and comparing the splendour that was, with the present misery and fears for the future, quite explains the rage of the Bordelais at the exasperating insect. As yet the renowned country of Médoc and Sauterne, where wines are produced which appear only on the most sumptuous tables, has not been attacked in a very sensible degree; but on the right bank of the Gironde, from Florac to Loussiac, from Loussiac to St. Croix du Mont, across the vast territory bordering the bend of the Gironde, desolation is at its height; and in the districts further distant, in Charente, Languedoc, and the south, the evil is almost irreparable. Four hundred thousand hectares of Vines have almost disappeared, and 200,000 more are threatened with a like fate. A third part of the Vineyards of France have been attacked, and the remaining two-thirds can only reckon on an uncertain future. An annual revenue of 150,000,000f. is lost to the nation, and a capital of three or four milliards has become unproductive.

Since I have been here I have heard many people of experience speaking of the Phylloxera and of the means available for combating it; I have myself carefully, and with the aid of competent guides, examined both the Vines and their enemy, and the conclusion to be drawn is that the problem of its extirpation still awaits a practical solution—one capable of producing results such as sulphur produced on the scourge of 1854—the oidium. As regards the Phylloxera, only palliative, preventive measures, have been tried, leaving it in doubt whether to attribute the disappearance or absence of the insect to them or to chance, the Vine perhaps being again suddenly ravaged and the futility of the treatment demonstrated. As soon as the Government found itself under the necessity of exempting the ravaged and unproductive Vines from taxation it gave the matter its attention. A prize of 300,000f. was offered to the inventor of a means of arresting or preventing the ravages of Phylloxera, and 500,000f. was voted in aid of the suffering Vine-growers. The prize of 300,000f. has given rise to projects enough; and as to the vote, it has served to convert a certain number of men into inspectors and reporters, who have still further increased the already rather rich collection of designations composing the French official world. The Vine-growers have still to choose between three courses—either to submerge the Vines, to subject them to injections of sulphuret of carbon, or to plant Vines of American origin. Submersion is only possible on the low-lying banks of rivers or canals. It has given very good results where the water serving for the submersion is slimy enough, like that of the Gironde, for instance, to compensate by a deposit of mud for the impoverishment of the soil the submersion in general produces. This is apparently the only result of the submersion, and it does not extirpate the insect, which in its winged state can escape. The mud deposited by certain waters richly charged with fertilising matters produces such a strengthening effect as to paralyze the enfeebling influence of the Phylloxera; but it must not be forgotten that the only Vines that can be submerged are those below the level of rivers or canals—that is to say the least important part of the Vines attacked or destroyed. The prolonged rains of this year led some Vine-growers to hope that, with the soil soaked, the terrible enemy would be overcome; but when the rains ceased and the sun had dried and warmed the Vines again there was the Phylloxera as before, and neither rain nor damp had harmed him. Submersion cannot deliver the Gironde from the ravaging insect; but it is well to submerge wherever it is possible with the slimy water of the Gironde, which if it does not destroy the Phylloxera, acts as a restorative to the ravaged Vines.

All who have had the opportunity of judging of its effect seem to be of opinion that sulphuret of carbon is an almost certain preservative for Vines which have not yet been attacked, or only slightly so. Sulphuret of carbon is a liquid which is applied by injection. Two men are required for the operation, one to drive the injection into the soil and another immediately to close the aperture so as to prevent any external evaporation. The operation requires to be performed by skilled workmen, and must be executed with great care, so that neither too much or too little of the substance be injected, and that it be at the proper distance from the surface and from the roots. Great precision is thus requisite and the opening must be immediately closed. The cost of materials and labour is calculated at 150f. to 160f. per hectare, and the operation being always necessary twice a year, this involves an outlay of 300f. or 320f. per hectare. In most of the Vineyards in Languedoc and the departments producing ordinary wines, such a remedy is inapplicable; for 30 hectolitres of wine per hectare being an average yield, when the price is from 15f. to 30f. a hectolitre, or 450f.

to 900f. a kilomètre, 300f. per hectolitre cannot be afforded for a remedy of uncertain efficacy; for this would swallow up the entire margin left by labour, transport, casks, &c. Sulphuret of carbon can only be applied to high priced wines. A third remedy is the substitution of American for French stocks. American stocks, first introduced by a wine-grower near Bordeaux, are alleged to be the origin of the malady, the American Vine not being injured by it, and in this Vineyard I have seen one of the American stocks with 150 bunches of black Grapes upon it. Whether or not American Vines introduced the disease, people are afraid of planting them where the Phylloxera has not appeared, lest they should introduce it; but they have been tried in ordinary Vineyards already visited by the Phylloxera, where there was no fear of the quality of the wine being impaired. In Languedoc wherever the American Vines have begun to yield the Vintage has shown an improvement, but nobody is able to say whether in the case of the best wines the quality would be unaffected. Some argue that the stock is immaterial provided the grafts and soil are good, and that equally good Médoc would be produced by American as by French stocks. But no grower has ventured on the experiment for fear the reputation of his wines should be forfeited. The Phylloxera having, however, been detected in one of the best Médoc Vineyards, it will soon be necessary to combat the invader. The planting of American stocks requires four or five fallow years, and few growers can afford this inter-erum.

Thus the problem remains unsolved; submersion being uncertain and of limited practicability, sulphuret of carbon being too costly, and replanting being slow and hazardous. Meanwhile nothing is more melancholy than the aspect of the infested districts. From the top of the hills all along Floirac, Loussiac, and St. Croix, you see large barren fields, lifeless houses, props without Vines clinging to them, unrepaired and unfrequented roads, peasants engaged in a hopeless labour. From time to time my obliging companion and guide pulls up; we alight and pick up an infested root. With a microscope we see the yellow active parasite which covers the root with a thick layer, and pronounces sentence of death on the whole plant. Sometimes my companion shows me a plant having no longer either parasite or sap, and exclaims, "The rogues have decamped after killing the hen that laid the golden eggs." This afflicting spectacle makes you understand the adjective *vastatrix*, and I eagerly accept an offer to take me to some of the best Médoc Vineyards where the vintage is actively going on.—*Times* Special Correspondent.

Leaf-soil.—There should be no lack of leaf-soil next year, as the present falling crop of leaves on all kinds of trees is one of the heaviest we have had for years. In large places enormous heaps will be put together, and in small gardens, instead of following the evil example of the London gardeners, and burning them, they should be built into tidy square heaps, and when sufficiently decomposed, be spread over the surface of beds and borders and dug in. Although

not rich in manurial properties, yet leaves are a most valuable dressing for the soil, and soon decompose, keeping the soil open and fertile. Leaves whilst yet fresh make good covering, especially for the blanching of Seakale and Rhubarb, and assist with part manure in making up a steady hotbed for Potatoes, seeds, &c. The avidity with which worms draw the fallen leaves into the soil shows that they serve other useful purposes besides those enumerated.—A. D.

Plants of Importance in Dairy Farming.—Drawings and dried specimens of the following plants were exhibited by the Berlin Agricultural Museum at a recent exhibition in Berlin of dairy produce:—1. *Plants that Promote the Secretion or Flow of Milk.*—The milky juice of the fruit of *Aspidosperma Quebracho*, used in the Argentine Republic. *Carica Papaya*, the Papaw: the milky juice of the unripe fruits and petioles acts like *Cirsium arvense*, *Cynara Cardunculus*, *Ficus Carica*, *Oxalis Acetosella*, *Piper nigrum*, *Quereus infectoria*, *Rumex Patientia*. *Galium verum*, the true (German) Milkwort, does not encourage the flow of milk. 2. *Plants that Hinder the Secretion or Flow of Milk.*—*Cochlearia Armoracia*, *Finguicula vulgaris*, also *Sanicula europæa* is believed to act in the same

manner. 3. *For Colouring Butter and Cheese.*—

Bixa Orellana, *Calendula officinalis*, *Carthamus tinctorius*, *Croceus sativus*, *Curcuma longa*, *Crozophora tinctoria*, *Daucus Carota*, *Morus tinctoria*. 4. *For Perfuming Cheese.*—

Melilotus corulea, *Penicillium glaucum*. 5. Plants which give a peculiar colour to the milk of cows feeding upon them:—

a. Colour reddish.—*Galium verum*, *Rubia tinctorum*, species of *Carex*, *Scirpus*, and *Equisetum*, of *Ranunculus* and *Euphorbia*, and young shoots of deciduous trees and Conifers are said to give milk a reddish colour.

b. Colour yellowish.—*Daucus Carota* and *Rheum palmatum*. *c.* Colour bluish.—*Anchusa officinalis* and *A. tinctoria*, *Butomus umbellatus*, *Melampyrum arvense*, *Mercurialis perennis*, *Polygonum aviculare*, *P. Fagopyrum*, and *Rhinanthus major*. 6. The following plants give a peculiar sharp taste to the milk of cows feeding upon them:—*Allium ursinum*, *Artemisia Absinthium*, *Brassica Napus*, *Gratiola officinalis*, *Euphorbia Cyparissius*, *Helieborus niger*, *Matricaria Chamomilla*, and *Zea Mays*.—*Wiener Landwirthschaftliche Zeitung*.

The Double Flowering Golden Feather is known in the trade as *Golden Gem*, and is a yellow form of the common green kind. The foliage is somewhat lacinated, but not so handsomely as Osborn's kind, which is the prettiest of all the *Golden Pyrethrums*. The *Golden Gem* was originally offered as a bedding plant, but one season's growth showed that it was useless for that purpose, as the habit is loose, and each plant runs off to flower quite early. It is easily raised from seed, and therefore can be made to produce a large quantity of white flowers. If grown as a flowering plant, no doubt the green-leaved kind is the best, because the contrast with the foliage is much more pleasing. For edgings, margins, and carpet bedding the *Golden Feather* still affords the best yellow, but the fact that it is so easily raised from seed causes it to be so widely used that it soon becomes a nuisance.—A. D.

The Sidney Oak, Tenshurst.

View in the Park at Stowe.

THE FAMOUS PARKS AND GARDENS OF THE WORLD.*

A book on this subject really well done would be a very attractive one, and also very useful. The present work is attractive in all that concerns good engraving and good printing, but the famous gardens of the world are after all but poorly represented, though there are a great many pretty cuts scattered through the book—many of them more interesting from the point of view of art and wood engraving than gardening. The book, in fact, is a sort of translation or abridgment of Mangin's work on gardens, and illustrated by many of its cuts. It has often occurred to me that a book of this kind really well done would be a most valuable

Grand Trianon." To which question I can only say that I hope not. Persia is a sad and blighted land in many parts, I believe, but I trust it is nowhere so sad as the ruins of the dreary rubbish which we owe to what is called the "genius of Le Nôtre." In this world, so far as I have seen it, I have never seen anything so dismal as the garden of the Grand Trianon; and the daub in imitation of it must indeed be deplorable. From this book one turns to think of what good might be done by well-selected views of gardens which are really famous and beautiful. Some of our own private places would form very attractive and instructive ones, but you teach nothing by merely figuring a house, as is so often done in this book, neither do you teach much by showing, as a "landscape garden in Ireland," one or two common trees on a bit of level ground, as on page 159. There are a great many beautiful gardens abroad which we do not know enough of in this country, particularly some of the German and Austrian places; but even to illustrate the really remarkable gardens in our own country would be a grand work.

V.

Kerosene for Insects.—A gentleman in San Francisco having in his conservatory various hard-wooded and thick-leaved plants covered with insects, tried, with only temporary success, the tedious and expensive plan of washing with soft soap; also syringing with various substances, including carbolic acid, which injured the tender growths. He then hit upon what proved to be a very effectual remedy, of which he says, in the *Californian Horticulturist*: I procured from a druggist an atomizer, and filling the bottom with kerosene, sprayed over a Camellia to be experimented upon. It was a very dirty plant, the branches and leaves of which were covered not only with scale, but with black fungus; a very small quantity sufficed to vaporise and cover the entire plant. After the fluid had evaporated and the plant was dry, the scales were found dead, shrivelled, and partly detached, and with the slightest touch fell off; the black fungus, also, which everybody knows is so tenacious on the leaf, was dried up into a loose powder, which a shake sent to the ground. I did not confine myself to the single experiment; but have since used kerosene in the spray on several other plants pestered and diseased with these parasites, Orange trees, &c. I have also tried atomized kerosene to destroy aphid on Pelargoniums and on

one, and, so far as I have seen, nothing of the kind has as yet been attempted. It is usually done by persons who, in illustrating a beautiful place, are almost certain to omit the features that have any beauty or interest, giving us instead some fountain, hard building, or fantastic vignette which may happen to catch the designer's eye. The writing of this book is of the poorest kind, giving antiquated and small unauthenticated twaddle about old flowers and old gardens without the slightest point of utility. Here, for example, is a bit about Persia. "Has Persia had its Le Nôtre?" "To this question we cannot profess to give either an affirmative or a negative answer; but its royal gardens, if the traveller Charlin may be credited, bear a close resemblance to a sketch or daub of the

* "The Famous Parks and Gardens of the World." Nelson & Sons, London and Edinburgh.

the soft and tender flower buds of greenhouse Roses. I destroyed the aphid, but the new and tender growth of my plants was destroyed also.—*New York Tribune.*

THE FLOWER GARDEN.

HARDY PLANTS FOR WINTER FLOWER BEDS.

PLANTS suitable for the decoration of flower beds, after the ordinary summer bedding ones have ceased to be ornamental, have at various times attracted the attention of those concerned in such matters, and, as usual in such cases, much difference of opinion has been shown as regards the class of plants suitable for the purpose. I therefore just here allude to two or three of very easy culture which I used to adopt for this purpose many years ago. They are easily obtainable, and here let me observe that I hold the requirement of a plant for winter decoration to be, that it should look well immediately it is planted, which is certainly not the case with bulbs and many other plants that are recommended for this purpose.

Helleborus fœtidus.—This used to be one of my greatest favourites for the decoration of winter beds. Its singular foliage of an evergreen character resembles that of an exotic Palm more than anything else, and, as plants of it could be taken up with good balls of earth, it was an excellent one to remove, and so hardy that we often planted it in vases elevated on the top of a wall, and exposed to the severest winter winds, without its suffering in the least; and its flowers, which appear at Christmas or before, are no detriment to it, which is the case with many fine-foliaged plants. It is, as I have said, a plant of easy culture, being, in fact, a native plant, but seed of it requires a long time to germinate, and it perhaps likes to sow itself under shrubs and in odd places, where it is often met with, and plants of 4 in. or 5 in. high have pretty foliage, although larger plants look better. It seems to like a chalky soil, or one abounding in lime, and most likely it is found wild only in such places as abound in these materials; but it thrives in ordinary garden soil, and when once obtained there are few but who would admire it. Many years ago I sent some plants of it to London to a person who occupied a high position as a decorator of public rooms and dinner tables, and he did not know it, but placed it amongst his choicest plants, and in the most prominent positions, and he may, perhaps, have increased his stock of it by this time, but it is not yet so common as it deserves to be. I believe that medicinally it is a poisonous plant.

Iris fœtidissima variegata.—This is a variegated form of the Gladwin, and is more persistent than most other kinds of variegated plants; at least I do not remember ever seeing it become green; and its foliage being at all times persistent, it is quite as useful as any of the Yuccas, and, being of easy culture, is more manageable. It is easily propagated by offsets, as it seldom flowers, and I never could make anything of it in that way; but when well grown it looks well either in summer or winter. The striking variegation of its foliage equals anything in that way that I know of. I presume its prototype to be a British plant, but I have never met with it wild.

Arabis albida variegata.—The merits of this dwarf plant are that cuttings or slips of it may be put in in November, and will invariably grow, looking well at first and all winter, and it may be planted as an edging around beds of something else, its neat-looking foliage contrasting well with anything around it. It also flowers at the same time as the green one, but for winter it is very handy as a dwarf plant.

Stachys lanata.—This woolly-leaved plant may be employed in the same way as that last named; slips of it grow equally well, and it is of easy culture.

Cineraria maritima.—Although plants of this do not transplant so well as some that are mentioned above, it may, nevertheless, be introduced here, and if all long slips of it be inserted in the ground up to their leaves they will mostly grow. Associated with it may be mentioned the two kinds of Lavender Cotton (*Santolina incana* and *S. Chamæparissus*) as described by your correspondent (p. 394), both of which I used to grow many years ago, merely distinguishing them by one of them being upright and the other spreading.

It will be seen from the plants named that their merits depend on their foliage, and that shrubs of various kinds may be added, but as these seem well known to all, I refrain from giving them here, but will only name one that is but seldom met with, and yet it is one of the most common and hardy of all, and that is the common Rue, the foliage of which looks very neat and pretty, and plants of it may

easily be obtained from cuttings, but the only place I ever remember to have seen it used with effect was in the garden of Mr. Mendell, near Manchester, where, in addition to the many other things for which this garden was famed, was a good supply of this plant being prepared for winter use. It is needless to observe that in addition to the above, plants remarkable for early flowering may also be introduced, and as they usually present a good tuft of foliage, their presence is equally acceptable in autumn and winter as in March or afterwards, although some of them, as *Arabis albida* often show flower in February, and the blue *Forget-me-not* soon after, but I leave it to someone else to extend this list.

AN OLD GARDENER.

ALPINE PLANTS AND ROCKERIES.

I AM afraid that Mr. Goldring has not mended the case as regards these plants by his last note. There is no doubt whatever that very often too much fuss is made over building rockeries, and, when they are built, they are of little use to grow plants upon. Allow me to point out a plan which I have adopted here—a very simple one—by which the conditions of success are secured, and the monotonous flatness obviated to which Mr. Goldring objects. It is nothing more than half sinking a few stones here and there in an ordinary herbageous border. For instance, close to where I write, two stones are placed almost touching each other, one has a perpendicular side which rises 9 in. or 10 in. above the ground, and faces north-east; at the base of this two or three plants of *Cortusa Matthioli* are planted; here it thrives luxuriantly, just enough shade is obtained, and its roots being in contact with the stone and under it are quite at home. On the top, in the chink between the stones, *Dianthus alpinus* is planted; here this thrives to perfection, and has spread on each side over the stones. In other cases, three or four, or more stones are half buried, and the space between—following the undulations of the stones—are filled with soil. One of these patches is planted entirely with *Phlox Nelsoni*, another with *P. setacea*, another with *P. verna*, and so on. The plants fill up quite closely all the spaces between the stones, and creep up them, and in such masses can be very well seen. In another instance, at the base of a stone *Dodecatheon integrifolium* is planted in a patch, and in a little slope up between two stones occur two or three plants of *Primula rosca*; at the base on another side *Primula verticillata* (this is planted out early in spring), and among the stones on the top may be seen *Saxifraga longifolia*. In another, several plants of *Saxifraga geranioides* are planted at the base of a stone, and the interval between this and another is filled with *Epimedium pinnatum*. In another a tiny standard, on a 6-in. stem, of *Cytisus atro-purpureus* is placed towards one side, and one of the double-flowered *Geuista tinctoria* on the other, and the intervals are filled with *Acaena microphylla*, and so on. All these groups are well varied and distinct, and it is quite endless the number of combinations a little taste will produce even with common materials; and all I have mentioned are common. It is the commoner, but none the less beautiful, plants that we want to popularise, and not those that are rare and difficult to cultivate; in fact, with many of these latter there is not enough of them to popularise with. A point that has generally been left out of discussions upon this subject is that most of these plants—one can scarcely tell why—look to best advantage when associated with stones; and there is the other fact that they not only look better, but do better. In all the instances I have quoted, none of the stones are more than 10 in. or 12 in. above the ground. I forgot to mention that in the group composed of *Phlox setacea*, close to the stones and towards the back, *Iris Pseud-acorus variegata* was planted, and this group was very charming.

T. SMITH.

Newry.

Useful Border Plants—After a sunless season and continual rainfall, causing a great scarcity of flowers, the names of such as have done well here may be acceptable. After a good bloom of Alpine Auriculas, Polyanthus, and others of the Primrose tribe, the first on the list is German Pansies, fancy varieties; these have kept up a good bloom during the whole season, followed by *Myosotis dissitiflora*, *Coronilla* (the herbaceous kind), *Trollius*, *Campanula glomerata superba* (a good useful variety), *Lupinus polyphyllus*, *Delphiniums*, *Hemerocallis*, *Canterbury Bells* (Dean's strain), *Sweet Peas*, *Antirrhinums*, *Pentstemons*, *Rudbeckias* (still in full bloom, November 8), *Fuchsias*, *Hydrangeas*, and that fine old but neglected creeper, *Tropæolum tuberosum*, which has been grand for a long time, and it is still in full bloom and seeding freely this season. These are everybody's flowers, so to speak, as, to a certain extent, they take care of themselves; it is, therefore, to be regretted that they are not more extensively grown than they are.—W. DIVERS, *Winton, near M. Stone.*

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Rare Plants on the Ormes Head.—In reply to a letter, signed Edwin Jackson, which lately appeared respecting the *Himantoglossum hircinum* (the great Lizard Orchis), I am somewhat surprised that it should have escaped the notice of Mr. Incehald. However, such is the case. In the year 1870 I planted a fine specimen (which I found on the "Little Orme") in the garden of the late Mr. A. Schofield, where I have no doubt it is still growing. This year I collected several specimens on the "Great Orme," all of which have bloomed abundantly, having from fifty to seventy flowers on a spike. I have also collected nearly all the British Orchidaceæ, among them was a variegated specimen of *H. hircinum*, near Dover; but I regret, however, that like many of our native treasures, they are becoming scarce, and unless they are taken in hand by propagators they will soon be exterminated. Thousands of choice plants are pulled up root and branch, and taken away annually by persons who do not know their value. I am propagating a large quantity of the Orchis from seed; and next year, I shall have many hundreds of the great Lizard, which I shall have much pleasure in presenting any botanical friends, who, like myself, take interest in this rare and beautiful class of plants.—GEO. SIMPSON, *Llandudno*.

The above extract from the *North Wales Chronicle* of Nov. 8 may be of interest to students of British wild flowers. The writer, who published his first letter under the signature of "Botanist," now reveals his name and address. He repeats his previous statement more emphatically and with greater confidence than before, that he has this year found the Lizard Orchis on the Great Orme, in which case he deserves the credit of finding it and adding one more to its few habitats; while to all students of wild flowers in this neighbourhood, it will be a great pleasure to add it to our local flora.—EDWIN JACKSON, *Llandegai*.

Iris Kämpferi Chelsea Hero.—This is a large and handsome double-flowered variety of Kämpfer's Iris, introduced from Japan. The flowers are flat and regular in form, 5½ in. across, of a rich blue purple, lit up by a golden bar at the base of each of the six segments, which are closely imbricated, and spread out horizontally. The breadth of the segments, and the complete imbrication of the inner over the outer series, give a peculiar fulness to the flower.

East Lothian Stocks.—At present (7th Nov.) there is a wonderful display of these beautiful Stocks in flower in the grounds of the Metropolitan Cemetery, Morningside, Edinburgh, showing how well adapted those fine varieties are for autumn work. Mr. Cowie, the superintendent, has been a most enthusiastic grower of the East Lothian Stock for many years, and has been the means of introducing several new varieties. To him we are indebted for the beautiful sort named New Crimson, which is a sport from the old scarlet, and also for the fine white Wallflower-leaved variety, which is a sport from the old white; this latter variety also originated with Mr. Shearer, of Yester. It would be well for growers of these Stocks to notice any tendency to sport in any of the single plants, as it seems to be the only way in which new kinds are to be obtained. This is my motive in directing attention to the above, as many are under the impression that it is only from seed that new varieties are to be obtained.—JOHN DOWNIE.

Variegated Grasses.—I can add two more to your correspondents' lists of these. I have *Poa aquatica* very clearly and regularly striped with white in the summer, but towards autumn the markings disappear, and it is not to be distinguished from the type. *Arundo Phragmitis* I found well variegated in a muddy hollow on the cliffs near here this summer.—J. M., *Charmouth, Dorset*.

Double-white Rocket.—I beg to thank Mr. Elliot for his kind suggestions (p. 404), whereby I might obtain a plant of this Rocket; but I am sorry to say that I am unable to do full justice to a plant that is so scarce and choice, and therefore I must decline the offer so kindly made. I hope, however, to live to see it again more plentiful than it is now.—AN OLD GARDENER.

Pea Haulm and Slugs.—Some few weeks back I requested one of our men to clear a south border of Pea haulm, but being Saturday night it was left on the border till Monday morning, when under the haulm I found the ground covered with slugs. Therefore taking time by the forelock, I immediately ordered small bunches of Pea haulm to be placed round all quarters on which young green crops were growing, and we now, with a basket of lime, go round these every other morning, merely turning the Pea haulm and dusting the hot lime over the slugs. In this way we are fast exterminating these arch foes to gardeners.—R. GILBERT, *Burghley*.

NEW KIND OF GARDEN LABEL.

LOOKING at labelling in a general sense, nothing, so far as private gardens are concerned, can be more unsatisfactory, especially those in which the collection of plants is of some magnitude. Nurserymen and the managers of public and botanic gardens have each a system of their own, more or less commendable, or, as the case may be, not to be commended at all. I well remember my first visit to the herbaceous ground at Kew about the beginning of April. At that early season the display of plants was meagre, the most conspicuous feature being the display of unnecessary large labels. Over conspicuity in this case prevailed at the expense of neatness; business men soon discover which is the most practical, permanent, and most economical method. In their case numbers are mostly used, and one of the most durable and effectual methods which I have ever seen was the Oak staves of foreign flour barrels, neatly split, sawn into lengths, and boldly burn-marked with a number, the nine figures being sufficient to denote the vegetation of the whole world. I cannot even glance at the almost infinite variety of labels used or recommended. A great error, I think, is committed in private establishments in overloading well kept and beautiful shrubberies with glaring white earthenware labels, with the name in black, burnt in. I consider that the natural grace and repose of many a beautiful shrubbery is wholly cut up and destroyed by these ostentatious attempts at the scientific, carrying with them, as they do, too much of the shop, the cabinet, and the museum to be at all agreeable.

Fig. 1.—Wire frame without label. Fig. 2.—Frame with label attached. Fig. 3.—Single strong wire perforated. Fig. 4.—Wire with label attached; c, ground line. Fig. 5.—Objectionable form.

To those who grow, say, perhaps, 1,500 or 2,000 herbaceous and Alpine plants, permanent stereotyped labels are an impossibility; to such collections something is continuously being added, or, it may be, lost, and in such cases labels that can easily be obliterated, and used over and over again, must be adopted. Hence we are thrown on the small, common, deal label, and all the vexations consequent on its inefficacy, the cause of which is too well known to those who are compelled to use them largely. The capillary nature of the soft deal converts it, as soon as it is thrust into the damp or wet earth, into a kind of sponge; its tissues get gorged with water, and the slight coat of paint and the pencil writing perish, and the label itself becomes decayed, and breaks off at the slightest touch. Another great source of trouble with these kind of tallies or labels is the effect of frost. Owing to the porosity of the wood, it is always warmer, even during the most intense frost, than the soil in which it is inserted, and a slight vacuity is formed around each label, which, thus loosened, is thrown on the surface, on the expansion of the soil by frost, to become dry, and to be blown about by the wind. The evil of this is more real than may be imagined. After the frost of last winter I had in my garden at least 1,000 labels lying in confusion, sometimes two or three together, and I have had to discard in my time a collection of *Sedums*, *Saxifrages*, and *Sempervivums*, and latterly a collection of *Epimediums*, owing to the obliteration and misplacement of labels.

To counteract this ever-recurring torment I have devised what may be called a combination label, wherein the common soft deal label, in conjunction with wire, will remain perfect for years. Fig. 1, A, is a piece of wire (it need not be too strong) doubled close together for about 7 in., expanded at the bottom 1 in. each way, and then bent downwards 3 in. to form prongs, to thrust into the soil. On the double portion of the wire a 4-in. label is placed, rising a little above the wire; the label is pierced with a small hole in the centre, and a tack or small bit of lead wire is passed through it and the doubled portion of the wire and clenched behind, forming a rivet, when the label has the appearance shown in fig. 2, A representing the rivet. When the prongs of the label are thrust into the

earth there will be 3 in. clear between the soil and the label, thus preventing it from being spoiled by damp, or being bespattered by the rain with dirt; and as a label is always supposed to be close to a plant, the elevation of the label by the wire is not noticed. Another form of these labels, and more simple still, consists of one straight piece of stout wire, such as is used for fencing, cut into lengths of 12 in. (fig. 3). This wire is heated, and a hole made through it as at B, against which the label is placed and riveted as before (see fig. 4).

Any ordinary workman, with a few tools and a square piece of iron fixed permanently on a bench as an anvil, would turn these out expeditiously, say twenty an hour, or, perhaps, what is better, a nailmaker would make them almost as fast and as cheap as nails. The wires need not be galvanised; tie them together, by means of bits of fine wire, into bundles, heat them hot, and drop them (*i.e.*, the bundles), into a vessel of tar; the wooden portion can be fixed on afterwards. Fig. 5 is a form of label I could not tolerate, though it is sometimes commended. When used in quantities its horizontal shape renders it too obtrusive.

THOS. WILLIAMS.

Ormskirk.

NOTES OF THE WEEK.

Winter Blossoms.—Amongst plants that cheer us in greenhouses in winter, the *Abutilons* are beginning to have a place. They are distinct in form from most other flowers to which we have been accustomed at that season, and some of them are very pleasing in colour. *Vilmorin's* red form of the Chinese Primrose is a real gain to the winter greenhouse, and quite distinct from the strains that have hitherto been raised in this country. The colour is a fine rich rose-red, very cheerful in winter. What with this and the *Cyclamens* and zonal *Pelargoniums*, also so much improved in variety and culture during the past dozen years, the glasshouse in winter has become very different from what it used to be.

Pansies.—We have received from Mr. Hooper, of Bath, some handsome blooms of Pansies, which, owing to the open state of the weather, are now flowering almost as finely as in summer. Amongst the sorts sent were *Wm. Gladstone*, rich yellow, with a dark centre; *Grand Duchesse*, lemon ground with maroon centre, edged with the same colour; *Duchess of Edinburgh*, pale yellow with dark centre; *Good Gracious*, a large, bold flower, purplish-maroon, edged with pale yellow, streaked in the upper petals; and *Grand Monarch*, a large velvety-dark flower, with a light-coloured eye.

The Imperial Dahlia.—It is surprising that this stately and lovely plant is not grown more than it is in private gardens. Several plants of it in the Palm house at Kew struck us as being very beautiful—so graceful and delicate in colour—although not what we should call very strongly grown. By the way, is there not some mode of growing or grafting this, so that it flowers in a comparatively dwarf state?

Torenia asiatica as a Curtain Plant.—There are now some plants of this old favourite at Chiswick hanging down 4 ft. from the bench on which they stand, associated with the variegated trailing Grass which is so useful as a curtain plant. This is too often the only plant used, whereas the *Torenia* is more beautiful, its foliage and stems forming a graceful curtain whether the plant is in bloom or not; but as it is generally in flower it is, perhaps, the most desirable of all plants for the purpose just named.

Tomatoes.—The Tomato is becoming such a favourite that anything which enables us to get a greater supply of it is worth noting. At Chiswick a number of plants are fruiting nicely in the upper and warmer parts of the roof of a half-span house, and to reach the glass they have to be trained by a back wall about 7 ft. high on single stems. It merely shows the adaptability of the plant to almost any situation. There are many spare places in hothouses and greenhouses in summer where Tomatoes might be easily grown in quantities, and to reach any vacant position they may be as easily trained to grow 12 ft. as 2 ft.

Chrysanthemums in the Temple Gardens.—The annual display of these fine autumn flowers is now on view, and will be till the end of the month. In common with other classes of plants, they are not so fine as they would have been in a more congenial season, but still the exhibition is an excellent one, and is highly appreciated, judging by the continuous stream of people who visit it. There are upwards of fifty varieties at present in flower, and amongst them are several of the newer kinds, such as *La Frisure*, with rose-coloured and singularly-twisted florets, which show their white under-surfaces, and *Nuit d'Hiver*, which, like the preceding, is one of the Japanese varieties. It has saffron-tinted blooms, with the under-surfaces of the leaves yellow. Associated

with these is the brilliant deep red *Mons. Crousse*, and the beautiful varieties *Empress of India*, the *Gazelle*, and *Marshal MacMahon*. *Elaine* is another beautiful kind, and one which is well shown, the pure white blooms being very large and of fine form. Conspicuous amongst others are also fine examples of *James Salter*, *Queen of England*, *Mrs. G. Kundle*, *George Glenny*, *Hereward*, and others of the better-known sorts.

Watercress in the Kitchen Garden.—Water is by no means necessary to the successful culture of Watercress. In the gardens at Chiswick there is a border of it quite fresh and vigorous, and probably it would be more agreeable to most people than that taken from the usual Watercress beds, which are not always free from impurity. No doubt the season has favoured the land culture of Cress this year, but in many places on north borders it could easily be grown from seed as a common garden plant. Certainly in the autumn and winter good crops of it could be raised. Much as Watercress is now used, it deserves still further use. Abroad there is no more agreeable vegetable product. The little bed of Cress, in which a small beef steak often reposes in Paris, is delicious as an accompaniment, and so it is with fowl. The simple way of growing Cress just pointed out should make it easily obtainable anywhere; whereas, now it is often more common in towns than out of them, and usually in a crushed and wretched condition.

The White-stemmed Bramble.—This is a most important plant in the autumn garden, the white or silvery stems being seen at a great distance, and the growth being very vigorous. It seems best in warm soils in the southern counties. The fruit is both edible and delicious. At the present moment there are strong specimens of it both at Kew and Chiswick.

Galax aphylla in November.—This modest little plant should be taken from the obscurity of the herbaceous beds in botanic gardens, and the mixed border in the few gardens in which it is grown, and cultivated as a really beautiful ornament of the autumn garden. Its leathery and shining little leaves are, as we write, a most effective elaret colour, and it would be very ornamental as groups or edgings in the choice collection of hardy plants.

A Silvery Tree.—At Kew, on the 10th of November, I was much pleased with the singular beauty of *Elaeagnus flava*, evidently a young specimen, it being the most decidedly silvery in hue of any tree I have seen. The under side of the leaf is quite silvery, glistening in fact, and when I saw the tree the margins of every leaf were turned up so as to meet, thereby exposing only the most silvery surface. I have noticed others of the same family giving strikingly picturesque effects, a particularly fine group being that in the Emperor of Austria's garden at Laxenburg, near Vienna, but this one at Kew is the brightest I have seen.—V.

Acanthuses in November.—Not a few of the things that used to be left in the solitudes of botanic gardens, and here and there in an old-fashioned collection, will one day prove to be really important elements in garden embellishment. Among these are the *Acanthuses*, which are now full of vigour and beauty, and therefore most useful in prolonging beauty in the open air garden in a mild climate like ours, where severe frost does not often come till the winter is nearly half over.

The Great Vinery at Chiswick is now worth seeing, a very good crop being ripe in it. The success attending the Grape culture here is to a great extent owing to the plan of replacing the old, but to some extent worn-out canes with young ones—a plan that is persistently carried out by Mr. Barron.

A Fine-leaved Climber.—*Cocculus indicus* is a name better known in the *Materia Medica* than in gardens, and yet it is, perhaps, for fine foliage the most valuable stove climber we have, and quite as good in a hothouse as the noblest varieties of Ivy are in the open air. The beautiful, large, finely formed leaves group themselves into picturesque masses of foliage, and make it one of the best plants that can be grown in a hothouse of any size. It may be seen at present in very good condition both in the Botanic Gardens, Regent's Park, and also at Kew.

Nerine undulata.—This charming bulbous plant, with its delicate rose-coloured flowers and wavy margin to its petals, is a most lovely object, and it should be more commonly seen in our greenhouses. I like it quite as well as some of the more showy kinds, and it seems of easy culture. It is in flower now plentifully.

Bauhinia tomentosa.—This plant belongs to a family that very rarely sees in private gardens, and yet it is a very beautiful flower—soft clear yellow, with one rich brown spot on the upper petal. Lovers of uncommon and rare hothouse plants might secure it. It is a stove bush, and one which we should like to see grown better than it can be in a miscellaneous botanic collection. We notice it in the Palm house at Kew.

Aralia Sieboldi in Flower.—Planted out and strong in a cool house, the flowers of this fine-leaved plant are not without beauty of a singular kind. The individual little heads somewhat resemble the flowers of the Ivy in shape, but they are borne in an enormous panicle, the whole being ivory white. There is a striking specimen of it in the temperate house at Kew just now. In pots the same plant is not at all so noticeable.

Agapanthus umbellatus has this autumn been in finer condition and more persistent bloom than I ever remember seeing it before. I have seven plants of it in 15-in. pots, with from six to eight spikes of bloom each; these have been in full flower for the last five weeks, and, should the frost spare them, appear likely to remain attractive for another month. The flowers of this plant are usually of comparatively short duration, but I attribute the exception this year to their late blooming and to the fine cool time which they have enjoyed during that period. I may add that one of my plants is a variety called major. It is in every respect superior to the old form, being taller, more robust, and yielding larger flowers.—J. M., *Charmouth, Dorset.*

Indigofera juncea.—This is a quaint looking greenhouse plant with rose-coloured flowers and very narrow leaves, which, well grown, might be an elegant object in a certain division of the greenhouse, trained on a slender pillar, or over an arch. It is in bloom in the temperate house at Kew.

D'Ombraïn Testimonial.—It is proposed that this be presented to the Rev. H. H. D'Ombraïn at the annual meeting of the National Rose Society, which will be held at the Horticultural Club, on Thursday the 11th December next. Therefore, those who wish their names added to the list of subscribers should signify the same at their earliest convenience, either to Mr. William Scott, 1, Old Bond Street, or to Mr. Edward Mawley, Addiscombe, Croydon.

Arundo mauritanica.—This noble Grass is now in bloom in the Victoria house at Kew, bearing green and most graceful large fox-brush shaped panicles, in some cases 2 ft. long. We believe it is hardy out-of-doors, but requires the hothouse to bring it into flower. As the name indicates, it is a native of the shores of the Mediterranean.—V.

Ruta albiflora.—Mr. Green brings us this delicately beautiful hardy Himalayan Rue. It stood out last winter at Pendell Court, and Mr. Green used to grow it in old times in that wonderful collection at Hillfield. It is a very curious plant, quite unlike the common Rue in its flowers, and with a light, graceful foliage like that of a meadow Rue. The pretty little white flowers are arranged in an elegant candelabrum-like manner.

A Good American Apple.—We noticed recently some excellent American Apples called the White Pippin. It somewhat resembles the Newtown Pippin, and is, we fear, often sold for that variety. It is a most delicious Apple, particularly excellent for cooking, and we should recommend everybody to try it who cares for a good cooking Apple. It is, or should be, sold for about one-third the price of the Newtown Pippin. It is sometimes called in America the Canada Pippin, is of the same class as the Newtown, and is said to be a very regular and good bearer. It is rather a large Apple—yellow, with small dots, and a dull blush, and, compared with other fruits, somewhat highly coloured. The flesh is very tender, and of a brisk juicy flavour. The more of these Apples the Americans send us the better. As has been stated it is a good culinary variety, and for eating it is also almost or quite as good as a Newtown.

Chrysanthemums at Slough.—The collection of these popular autumn-flowers in Mr. Charles Turner's nursery will be well worth a visit shortly, as it comprises, besides the majority of the older varieties, many novelties of decided merit. The principal show house is a light, airy structure, admirably adapted for showing the blooms off to the best advantage. It is scarcely necessary to add that this collection, in common with most others, is not in such fine condition, owing to the ungenial season, as we have hitherto seen it.

North-western Amateur Chrysanthemum Society.—The annual exhibition of this society was held in Milton Hall, Hawley Road, on Monday, Tuesday, and Wednesday last, and was numerously attended. Both plants and cut blooms were also abundant and good in quality. Mr. Newman obtained a silver cup for the best twelve cut blooms incurred—a beautiful exhibition. Special prizes were taken by Mr. Leggett for the best cut Pompones—very good specimens. Mr. Charlotte was awarded a silver cup for twelve fine plants. Mr. Brown, jun., won a prize with all the varieties exhibited by him, amongst which Mrs. George Rundell was conspicuous, and Golden Christine secured a reward to Mr. Morris. The table decorations of Mr. Bishop were very tasteful, especially the centre-piece, a vase of cut blooms.

Seaforthia in Fruit.—In the Palm house at Kew a tall, stately, and graceful Palm (*Seaforthia*) bears a beautiful drooping panicle of fruit—the whole fruit and stem ivory white, and the plant one of the most graceful objects in the vegetable kingdom.

THE KITCHEN GARDEN.

AUTUMN-PLANTED POTATOES.

If any propose to test the value of autumn planting Potatoes now is the time to do so. There can be no doubt that in a state of nature the soil is the proper place for the tubers during winter, and, without doubt also, they there keep sounder than when exposed to the air, notwithstanding all that may be said to the contrary. It is a common experience that the strongest plants invariably come from self-planted tubers, and where such is the case as good results may well be looked for from those properly planted in the autumn. There are, however, several conditions to the success of autumn-planted Potatoes that must be observed, and, unless these are observed or exist, it will be better to refrain from planting till the spring. In the first place the soil must be of a light friable texture and not retentive of moisture; then slugs, grubs, and wireworms must not abound; next, hard frost must be excluded from the sets; and, not least, plenty of space must be allowed between the rows, that a good covering of soil may be placed over them for protection. The best kinds for autumn planting are late and medium late sorts, but late ones are specially suitable for the purpose, as, if planted now there will be no undue excitation of growth until late in the spring. Early kinds planted now would doubtless throw up growth in March, and thus be killed back so far as to render the seed valueless. Not less than 3 ft. should be given between the rows, and when the sets are planted they should be put in open furrows, so as to admit of a liberal dressing of lime and soot being cast around each. This would prove most efficacious in keeping grubs, slugs, and wireworms at bay. With plenty of space between the rows, and the sets planted quite 6 in. deep, it would not be difficult to cover them over to a depth of 12 in. with light dry soil, and this ought to exclude all frost from the seed. In the spring several inches of this mould may be drawn off again, and thus the soil beneath, protected from heavy rains as well as frost, would be light and porous for the young shoots to come up through. It is the possible danger from frost and from vermin, and the possible collapse of the seed tuber from disease that tend so much to keep planting over till the spring. Without doubt, next to autumn planting, the present common course of keeping the seed tubers exposed to the light and air is the best, as it prevents undue excitement of the eye-buds, and the tuber is not exhausted before planting time arrives.

A good deal is still written about the deterioration resulting from clamping, and that it is the chief cause of the Potato disease; but all good growers house their seed on the soundest principle, and they unfortunately do not escape disease more than their neighbours. For late kinds it is, without doubt, advantageous that they should be induced to mature their crop as early as possible, and autumn planting on dry soils does conduce to this, as well as to the production of a better crop. Like bulbs, Potatoes throw out roots in the dark, and get well established in the soil before foliage is made, and no doubt self or autumn-planted Potatoes get in this sense a good start ahead of tubers planted in the spring, and therefore an earlier and larger crop results. A. D.

Magnum Bonum and Champion Potatoes.—In offering a few remarks on these two Potatoes, I am sorry that I cannot date my experience from some "hall" or "castle," so as to give them some weight. However, I live in a very large garden, where the Potato is, perhaps, grown as well as anywhere in the country; I mean nearly one-half of Lancashire. It is in such places where experience may be learned about any given variety of Potato, and reports, even from a dozen well-ordered private gardens, must be unsatisfactory compared with those from a dozen Potato parishes. At the present moment the Champion is pre-eminently the champion—the Potato of the day and of the market; the latter fact being the crucial test of the value of an article, as the Champion has superseded that very famous Potato, Paterson's Victoria, and at the present time is fetching the highest price obtainable for Potatoes, and has proved to be the best disease-proof Potato ever grown, not even excepting the once famous Fluke. How long it will maintain this position is a problem. The law of the Medes and Persians cannot apply to the quality or durability of the Potato. As to *Magnum Bonum*, I may say it is a misnomer; take away the "B onum" and leave the "*Magnum*," and the name may be descrip-

tive; a very fine handsome Potato, far better on the exhibition table than in the kitchen, and, so far as eating is concerned, having very little "Bonum" about it. This is the verdict of a jury composed of most of the Potato growers in these parts, and, more important still, that of the buyers and sellers. Soil and locality no doubt have a good deal to do with the quality of a Potato, and I believe that soap ball, the Early Rose, is fairly good when grown almost in pure sand. There is a famous Moss-land Potato grown in these parts called Skerry Blues, one of the coarsest-looking Potatoes known, all knobs and eyes, like a Jerusalem Artichoke, but when cooked well fit for a Royal table. In conclusion, I may add that any remarks or reports on the Potato must only be considered temporary—for a time and a season; and I am afraid that Mr. Buines' observations on the Potato must be rather considered historical than otherwise, as they have very little to do with the "Potatoes of the period," as a Potato that has held its own longer than any other—the early and universally grown Pink-eyed Kemp—is not even alluded to.—THOMAS WILLIAMS, *Ormskirk*.

Parsnips.—These useful roots have apparently enjoyed the cool wet season, being generally one of the best crops of the year. It is to be regretted that they are not more generally grown and appreciated than they are, as a large quantity of useful vegetable food might in their case be grown on a small area, and, in a season like the present when Potatoes are badly diseased, and such as are sound not up to the usual standard of excellence, any good substitute is welcome. In addition, too, to being easily grown and not much affected by disease or pests that ravage other crops, the Parsnip will keep in good condition during the whole of the winter and spring months. I find the Student and the old Hollow Crown variety to be all that can be desired as regards sorts, and if sown in drills 18 in. apart in March, in deeply cultivated soil, and thinned out as soon as the rows fairly show themselves, kept clean by frequent hoeings during the summer, and lifted as required for use in winter, and the remnant lifted before growth commences in spring, and stored in a cool cellar, they always form a useful reserve vegetable, doubly valuable when green crops fail, or are cut off by frost.—J. GROOM.

Peas at Darley Abbey.—On visiting Darley Abbey a few days ago (about the 3rd Nov.) with a friend, we found Mr. Keetley still gathering Peas—fine luscious Marrows with large well filled pods such as we have never before seen so late in the season. We shelled and tasted, and made notes, Mr. Keetley informing us that it was a new Pea named Culverwell's Giant Marrow. It had been sent to him for trial; he thinks very highly of it, and, judging from what we saw and tasted, this bids fair to become a general favourite, being larger in pod and Pea than the well known Telegraph, and a very heavy cropper.—VISITOR.

Disease-resisting Potatoes.—So valuable is a Potato like the Champion in this season of disease, that too much can scarcely be said in its praise, particularly where Potatoes have to be grown on cold clay, as they are in this locality, and where most other sorts are nine-tenths diseased, while the Champion is a good crop, in which there is scarcely a diseased tuber; but what I wish to call attention to is the quality. Last season, when the Champion was cooked, it turned out quite solid; but this season, being almost sunless and wet, it turns out like a ball of flour. Other sorts are generally just the reverse. The next best Potato to the Champion is Skerry Blue, which is small, but pretty free from disease. In the light soils of Cheshire this variety is excellent, but the old favourite, Paterson's Victoria, under another wet season will clearly be stamped out by disease. Magnum Bonums are scarcely at all grown hereabouts.—JAMES SMITH, *Waterdale*.

The Champion Potato.—Mr. Elwes, writing to the *Gardeners' Chronicle*, in confirmation of a statement by Mr. Cannell, says:—I planted 15 cwt. of Champion on poor, light, limestone brash with very little manure, and as the land was by the end of the summer quite overgrown with Couch, Clickweed, and wild Sage, I did not expect much of a crop. Side by side with the Champions were planted 10 cwt. of Paterson's Victoria, a good strain from Scotland, and 5 cwt. of Scotch Regents from a market grower in the neighbourhood. Of the Champions hardly any were diseased, and the crop was about 3 tons; of the Victorias, half were diseased and the crop about 14 cwt.; of the Regents nearly all were diseased and the crop only about 3½ cwt. I have always hitherto believed that for hardiness, produce, and quality Victorias were the best field Potatoes, but, though Champions have the great disadvantage of deep and numerous eyes, and are not so salable as Regents or Victorias, I should certainly recommend them as a poor man's Potato, on bad land, in preference to any other I have tried.

—Mr. Buggins, Woodlands Castle, Clonsilla, Dublin, also speaks favourably of the Champion. He says:—We have just ploughed up about 2 acres of Potatoes, namely, White Rocks, Kemps, York

Regents, and the Champion. The result in the case of the first three varieties is the same as those mentioned by Mr. Cannell, while the Champion has turned out a sound, clean, and good crop. Taking into consideration the heavy and cold soil of this locality, and the extraordinary season that has been experienced by us, I think this Potato has proved itself worthy of notice; and where large quantities are required for a winter supply, people will undoubtedly find this variety one upon which they may rely; at the same time, perhaps it will be advisable to hear an account of its keeping qualities at the close of the season.

EFFECTS OF THE SEASON ON FRUIT TREES.

It will, I think, be found that this exceptionally wet, sunless season has exercised a most baneful influence upon many fruit tree plantations. Not only is the fruit crop scanty, and the quality generally poor, but I much fear that in many instances a very serious injury has been inflicted upon the trees—an injury from which they will scarcely ever thoroughly recover. A writer in a contemporary expresses the opinion that the injury in question is due to blight and caterpillars; I am myself strongly of opinion that to unsuitable soil and defective drainage, in combination with a cold, ungenial atmosphere, may be traced the miserable condition in which many fruit tree plantations are to be found at the present time. The conclusions at which I have arrived upon this subject are based upon observations which I have had the opportunity of making this summer. I have invariably found that when the trees were growing in unsuitable soil, or where they could easily penetrate into a cold subsoil, or where the situation generally was cold or otherwise unfavourable, they have all more or less suffered. In many instances old trees are killed outright; and young plantations, which hitherto have grown vigorously, have become prematurely old, and are now presenting a lamentable appearance, the foliage being long since turned to a sickly yellow hue, and the entire aspect of the trees denoting extreme distress. It is very doubtful if such trees can again be depended on to produce good fruit, for if once the wood of the Apple and Pear tree becomes knotted and the growth checked, they scarcely ever appear to regain their normal vigour. Where, on the contrary, the trees have been well cared for, and good judgment brought to bear upon the selection of situation and the preparation of the soil, not only do the trees appear not to have suffered, but they actually seem to have rejoiced in the excess of moisture which has this summer been so inimical to most forms of plant life.

An illustration of this may be found in the fruit trees in the kitchen garden at St. George's Hill, Byfleet. A more healthy growth than they have made it would be difficult to conceive, the foliage being broad and lustrous, the wood vigorous but hard, indicating a most perfect condition of the functions of nutrition, and giving promise, should we be blessed with a favourable spring, of a bountiful crop of fruit. The difference between these trees and many others in the immediate neighbourhood is so great that a few words concerning them may not be considered out of place, and may perhaps be acceptable to intending planters.

Adverse seasons often afford valuable lessons, they teach us what to avoid, and it behoves us not to forget that which we have to pay so dear for. With respect to the trees in question, their success may be attributed to the care taken to ensure the conditions necessary to their well-being. In the first place, when the garden was formed extreme precautions were taken to ensure perfect drainage. Five drain pipes were placed together at intervals of 10 ft. in two layers, thus making provision for aeration and the quick discharge of all surplus water. In this manner the drainage was certain to remain good, the natural consequence being that the roots have never suffered from the large amount of moisture which has this year passed through the soil. The soil itself was also thoroughly stirred, and, if I remember rightly, a considerable amount of charcoal dust was incorporated with it. Since the trees have been planted the garden has been well manured and stirred, and cropped in the ordinary way. I should add that the garden is encircled by forest trees, which afford a certain amount of shelter, but do not exclude sun. What has been done in one place may be effected in another, for although unfavourable situations cannot, even with the best of care, be made to equal those naturally fitted for the growth of fruit trees, yet much may be done to improve them. Perfect drainage, shelter, and a well-stirred and properly enriched soil constitute the main elements of success in the culture of our hardy fruits. If any one of these essential points be neglected, failure at some time or other will inevitably occur. I have been induced to dwell somewhat at length upon this subject as I have this summer seen so many instances of lamentable ignorance displayed in planting fruit trees. Only a few days since I remarked two orchards of young trees, extensive plantations, both of which have not and can never be anything but a source of disappointment to

the owner. The trees have been planted without any previous preparation of the soil, and apparently without any care having been taken to ensure good drainage. I need only mention that Rushes are growing luxuriantly around the trees to afford a pretty accurate idea of the character of the soil in which the roots have to work. It is almost needless to say that the wet summer has nearly killed the trees, and where still alive they will never make any satisfactory progress. Planting in this manner is simply waste of time and money.

J. C. B.

GARDENERS' FRIENDS.

SYRPHUS PYRASTRIS.

THE flies belonging to this genus are very common, but comparatively few persons, when they see them hovering in the sunshine or settling on flowers, know what a debt of gratitude we owe to these insects, and of what immense benefit they are in our gardens and fields, or how different our flowers and crops would be were it not for the assistance we receive from the grubs of these flies in destroying the aphides which so overrun vegetation. These grubs may very frequently be found on plants which are attacked by aphides, and persons no doubt often kill them when destroying the aphides, imagining that their plants are suffering from the combined attacks of grubs and green fly. In this they make a great mistake, as one

Syrphus pyrastris.

of these grubs will clear a shoot from aphides in a comparatively short time, and in no way injure the plant. These grubs are long and soft, and are widest at the tail, and gradually taper towards the head, which terminates in a point; they are semi-transparent, and green or yellowish in colour. *Syrphus pyrastris* belongs to the Natural Order Diptera, or two-winged flies, and the family Syrphidae. The genus *Syrphus* contains twenty-eight species, whose economy is very similar. Nearly all the species are of a dark colour, with white or yellowish bands on the body, but in some species the bodies are much rounder and narrower than in others. Sometimes persons take them for wasps, and it is fortunate, therefore, that they are endowed with the power of rapid flight, for if otherwise ignorant persons would often kill them. The flies may be found almost everywhere from the end of May to the end of October, and are so common that Mr. Curtis has stated that he believes that they are in a great measure the cause of the incessant buzzing which may be heard on still warm days in the country. These are the flies which may so often be noticed hovering in the air like a hawk, in the sunshine under trees, or in some sheltered place, with their wings vibrating so rapidly as to be almost invisible. They will remain for some moments apparently motionless, and then suddenly dart off with the greatest rapidity. It requires a very quick hand to catch them, even with a butterfly net. The females have the instinct to lay their eggs, which are white and reticulated, singly on

the stems and leaves of plants infested with aphides. The little grubs are soon hatched, and at once begin their career of slaughter. As they have neither eyes or legs it might be supposed that they were quite helpless, but the reverse is the case. The underside of the last joint of the body is provided with tubercles, with which it manages to hold on to the plants pretty tightly, and its mouth is furnished with a kind of double-pointed hook. When it wishes to move it extends its head as far as it can, and lays hold of the substance on which it is with the points of its hook, and draws its body, contracting it as much as it can, as far forward as possible, and then again extends itself. In this manner it proceeds at a tolerable pace. Thanks, however, to the forethought of its mother it does not often require to move much, as it is surrounded by its prey. It is very interesting and amusing to watch one of these grubs feeding. It attaches itself firmly by the posterior half of its body, and, raising its head and the front part of its body, strikes boldly and quickly right and left until it touches an aphid, which it immediately seizes, and, holding it up in the air (see the figure) so that the insect cannot lay hold of anything to assist it in escaping, sucks it completely dry, turns its head towards one side, drops the empty skin, and begins searching for another in the most business-like way. I have seen one suck out the contents of a full-grown Rose aphid in a minute and a half. They will continue eating one after the other as fast as they can for some time. When full grown they attach themselves by the tail to a stem or leaf, and assume the chrysalis state. Whilst undergoing this change they alter their form very much; instead of gradually decreasing in size from their tail towards their head, the tail becomes very narrow and the head much enlarged, so that when the transformation is completed the chrysalis has much the form of a small Pear hanging against the stem. The chrysalis is formed by the skin of the grub contracting and hardening, and not by the grub casting its skin and appearing as a chrysalis. The insect remains in this state about a fortnight, when bursting open the larger end of its case, it emerges as a perfect fly. The grubs are often attacked by a small fly, one of the Ichneumonidae, whose grubs are parasitic in their bodies. Those which have been attacked become much darker than the others, and look unhealthy. *Syrphus pyrastris* is about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. in length, and measures across the open wings about 1 in. The head is yellowish, with large coppery eyes and small black antennae. The thorax is of a shining metallic bluish-green colour, fringed with yellow hairs. The body is oval, flat, and shining, black or bluish-black, with a long yellow or white curved spot on each side of the first three joints; these spots nearly meet on the middle of the back, and sometimes those on the second and third joints do join; the two following joints are edged with yellow posteriorly. The legs are yellowish-brown, the base of the thighs and the feet being rather darker than the rest of the legs. The wings are colourless, but are slightly iridescent, with dark brown nervures. The grubs, when extended to their full length, are about $\frac{1}{2}$ in. long, narrow, and fleshy, gradually increasing in width towards the tail; they are greenish or yellowish in colour; on either side of the middle of the back is a broad white line; these lines join near the end of the body; between them the back is purplish, and so transparent that the internal organs of the grub are clearly visible, and their movements can be seen with ease. At the tail of the grub, just behind the white line, is a double-headed tubercle, which is connected with the breathing apparatus. The chrysalis is about 3-10ths of an inch long, and shaped like a flask or Pear. When first formed it is of a pale pinkish-brown with darker brown markings in front down the middle.

G. S. S.

Euphorbia Juice Preserving Iron from Rust.—The protection of ships' bottoms from corrosion has proved a difficult problem to owners; but the fortuitous discovery that the juice of plants of the Order Euphorbiaceae, common and luxuriant in tropical climates, preserves iron from rust, is likely to be usefully applied to the preservation of those portions of ships below the water-line not only from corrosion, but from fouling. It seems that during the survey of Natal, some two or three years ago, one of the officers found that, when certain plants of the Order named were cut during the clearing, the knives were firmly coated with the abundant gum which exuded from them, and that the knives thus coated did not rust. In consequence, experiments with the gum in question were afterwards made by Sir Andrew Clarke, who some two years ago had a sheet of iron coated with it immersed in the waters of the Chatham Dockyard, where everything becomes rapidly foul. On being taken out it was found to be quite clean. The gum is intensely bitter and poisonous, which prevents the adhesion of marine animals to any substance with which it may be covered, and, as the plants supplying it are found in abundance on the seaside in low latitudes, even if this agent should prove only moderately efficacious, it may prove of great service to the shipping interest.—*Iron.*

ANSWERS TO CORRESPONDENTS.

Diseased Orchid Leaves.—G. T. W.—We cannot account for the deep discoloration of the leaf belonging to *Angraecum eburneum* sent. Its cells are decomposed and deeply discoloured—there is no fungus inside or out. Not being on the spot we cannot suggest a cause for such a state of thinness, and it is far more difficult to suggest any remedy. The leaf examined was surcharged with moisture, and this may possibly suggest a hint for future treatment. One requires to know the complete surroundings of a diseased plant before an opinion can be expressed respecting it.—W. G. S.

Fibres Used in Brush-making.—You will oblige me by giving the botanical names of plants yielding the various fibres used in brush-making, viz., Kittool (dyed black and oil drawn, so far artificial), Mexican fibre, Piassaba or Bass, Monkey Bass, and Whisk. I have heard that Whisk is a Grass called *Holcus Sorghum*, but all specimens do not seem to be alike. I consequently fancy two or three different species of Grass are used, and called Whisk indifferently.—TEE PEE. [The fibres referred to as being used in brush-making are produced by—1, Kittool—*Caryota urens*; 2, Mexican fibre—*Agave americana*; 3, Piassaba or Bass—*Attalea funifera* and *Leopoldinia Piassaba*; 4, Monkey Bass is probably the same as the last; 5, Whisk—*Sorghum vulgare* and *Cymbopogon Gryllus*.—J. R. J.]

Pelargonium Cuttings.—Can I take cuttings of these and strike them now? Do *Pelargonium* need heat in winter?—J. P. [It is not advisable to strike *Pelargonium* cuttings now, it should be done in spring—say early in March—as then the old plants, if cut back, will at once break again, and the cuttings will also soon make roots and will not suffer from damp. Heat would be injurious to all the year; all that is needed is to keep out frost; but extra heat in spring will be of great service, as that is the natural season of growth.—A. D.]

Begonias losing their Leaves.—J.—*Begonias* belonging to the tuberous-rooted section die down in winter; but they will re-appear in spring. Your plants, being in pots, should be gradually dried off, but not shaken out from the soil, as this is better done when the roots are re-potted in spring. A gentle heat is necessary to keep the plants in leaf and bloom at this time of the year.—D.

Preserving Carnations in Winter.—A.—Carnations are very hardy, and rarely suffer from frost, except when very severe, when a few small branches of some ever-green stuck around the plants should protect them fully. Keep cutting east winds often do more damage than frost, but any little protection is worth giving in order to assure the safety of the plants.—D.

Plants for Arbours.—Will you kindly furnish me with the names of a few common plants with which to cover an arbour?—B. [Plant the common Banksian Rose, which is fairly evergreen and a strong grower, and the Japanese Honey-suckle, which is also evergreen, and makes a dense cover. Either of these should mix well with Ivy, which is after all the best of climbers. *Jasminum nudiflorum* is also a good plant to furnish bloom for the winter.—D.]

Rudbeckia purpurea.—Can any one tell us what has become of this *Rudbeckia*? or where it can be bought? It has quite disappeared from the land! The name used to appear in several herbaraceous catalogues, but now I can find it none.—C. W. DOD, *Edge Hall*. [Probably you find it catalogued as *Echinacea*, which is synonymous with *Rudbeckia*. The variety intermedia of *E. purpurea* common enough in any of the large hardy plant nurseries.—W. G.]

Names of Fruits.—G. W.—1, Seckel; 2, apparently Marie Louise.

Names of Plants.—J. A.—1, *Nephridium invisum*; 2, *Polypodium Billardieri*.—W. R.—1, *Aspidium acrostichoides*; 2, *Aspidium falcatum carotidatum*.—H. W.—1, *Asplenium Belangeri*; 2, *Aspidium aculeatum lineare*; 3, *Nephridium Shepherdii*.—C. T. D.—1, a *Pellaea*, probably new, sent mature front; 2, *Asplenium lasiopteris*; 3, *Asplenium Filix-foemina furcillatum*.—*Phenix*.—1, *Selaginella Braunii*; 2, *Nephridium setigerum*; 3, *Pteris serrulata cristata*; 4, *Asplenium umbrosum*; 5, *Pteris tremula*; 6, *Spiraea Filipendula fl.-pl.*—*P. L.*—1, *Cystopteris fragilis*; 2, *Adiantum cuneatum*; 3, *Pellaea rotundifolia*.—G. W. O.—*Asplenium Filix-foemina pannosum*.—A. R. W.—2, *Begonia Richardsii*; 3, *Begonia near nitida*; 5, *Begonia angularis*; 6, *Begonia semperiflorens*; 7, *Begonia Hübene Uhler*; 9, *Begonia papillosa*; 10, *Begonia Ingramii*; 11, *Cystopteris fragilis dentata*; 12, *Blechnum occidentale gracile*; 13, *Polypodium Robertianum*.—J. W.—*Pyrus Aria obtusifolia*.—*Conifers*.—Next week.

Maple Leaves.—Ann.—The black blotches on the leaves sent are the work of a fungus called *Rhytisma acerinum*.—W. G. S.

Stobæa purpurea Seeds.—Some time since you had a coloured plate of this hardy plant. Can you tell me where I can procure some seed of it?—T. L. O. [Try Mr. Thompson, Tavern Street, Ipswich.]

Questions.

Double White Violet.—With me the Violet is a natural weed, and sometimes intrusive, growing and overwhelming other plants; therefore when I learnt that a double white one could be had, I at once secured a clump, and planted it where its relatives, the common blue and white, grew most advantageously, not in the least doubting its ultimate success. For two seasons, however, I have been doomed to disappointment. The original clump now represents more than a square yard of luxuriant leaves, but I have only seen three or four flowers and a few buds, the latter curling up and dying off soon after their appearance. From what I have seen of the flowers it is a Violet that deserves the utmost attention. They were as large as a fourpenny piece, extremely close in the petals, and strongly perfumed. If any of your correspondents have tried this Violet and have succeeded, I should be thankful to learn the treatment which it requires; and to those who like to cultivate it I may say that no pains or trouble will be thrown away to succeed with it.—W. T.

Neapolitan Violets.—This year I have planted these out in summer taking off the runners, and moving them to the greenhouse in September; but up to this time no flowers are visible; however, I do not despair, for it is evidently a late flowering variety, as such flowers as have been seen did not appear till the beginning of May this year. Every possible care was taken with the soil and drainage, the former being some of the garden soil in which Violets grow naturally; to this was added yellow loam and sand, the whole being well incorporated. The point upon which I am inclined to speculate is some stimulant, and therefore I am induced to ask what manure may I use with safety, seeing that all the Viola tribe are injured by using manure?—W. T.

Hornbeam Trees.—Will some of our readers inform us where the largest and best Hornbeam tree is to be found?

Rare Plants.—Will any reader be so kind as to tell me where I could procure *Lobelia Tupa* by purchase or otherwise? It is also called *Tupa Feuillet*. I find great difficulty in obtaining some other plants such as *Narthex asferida*, of which neither plants nor seeds appear to be derivable from any of the usual

sources. *Ferula persica* is another fine old plant I have long sought in vain. *Vella Pseudo cytistis*, *Nelumbium luteum*, and *N. aspericaule* are others which I desire to possess, and to that end shall be thankful for any information.—B. W.

Fuchsia Tom Thumb.—Will any reader of THE GARDEN kindly tell me the origin of this pretty dwarf hardy Fuchsia.—J. G.

Saddle Boilers.—I should be much obliged if any competent or engineering authority would explain satisfactorily in what respect a plain saddle boiler is inferior in principle to a terminal-end, a winged, or flued saddle, or any other form of horticultural boiler now in use, the heating surface in both cases being equal?—J. S.

St. Pancras Gardens.—Lady Burdett-Coutts has recently presented to the vicar, churchwardens, and vestry of St. Pancras what is termed a memorial sun-dial, standing upwards of 30 ft. in height, and erected at the expense of Lady Burdett-Coutts at a cost of upwards of £2000. It is intended to commemorate not only the reclamation of the disused and dilapidated burial grounds and their conversion into a beautiful ornamental garden for the recreation of the poor, but also those whose remains were known to be interred in the two ancient burial grounds of St. Pancras and St. Giles's-in-the-Fields. The memorial stands in a prominent position in the garden near one of its western main entrances, within a space corresponding to that of the mausoleum erected by the late Sir John Soane. It will be recollected that the vestry of St. Pancras, with the approval of the ratepayers and the assistance and sympathy of Baroness Burdett-Coutts, the Duke of Norfolk, and others, successfully resisted the attempts of the Midland Railway Company, who had already obtained by an Act part of Old St. Pancras Churchyard, to further encroach upon that as well as the adjoining cemetery of St. Giles's, in which the last interment was made in 1853. It was determined, if possible, to retain and preserve with due respect grounds which had afforded for centuries a resting-place for some of the most illustrious personages of their age, although both grounds had attained a most deplorable condition, and the vestry having secured an Act of Parliament to do what was required, succeeded in converting them into very beautiful gardens, taking care at the same time to preserve all the sacred relics of antiquity existing. Lady Burdett-Coutts determined to show her sympathies with the project for utilising the grounds for the recreation of the public, especially the poor of the surrounding neighbourhood, and for the preservation of the names of those eminent persons whose remains had been buried therein, by the erection of a memorial fittingly to record the names of some of those celebrities whose memory should be handed down to posterity. These gardens were opened by Sir J. McGarel Hogg, M.P., chairman of the Metropolitan Board of Works, and on the same day, June 28, 1877, the Baroness laid the foundation stone of the memorial now completed.

Royal Horticultural Society.—At the meeting at South Kensington next Tuesday there will be an interesting group of double Primulas, a fine show of Potatoes, a collection of Abutilons in flower from Chiswick, and, it is hoped, some good stands of Chrysanthemums. The competition for Messrs. Sutton & Son's special prizes for vegetables promises to be very spirited.

Government Prize for Phylloxera.—The conditions of the prize of 300,000*fr.*, offered by the French Government for a remedy for the Phylloxera will be forwarded to any applicant by the Ministry of Agriculture and Commerce. Englishmen of an inventive turn may easily, therefore, ascertain on what terms the reward is promised.

Waterproofing Boots.—A good composition for rendering boots proof against snow and wet, can be made of one part mutton tallow and two parts beeswax, melted together. Of course it will be more difficult to make boots thus treated take a good polish, but after a few times they will be as susceptible of a brilliant polish as ever. Half an ounce of Burgundy pitch, dissolved in half a pint of drying oil, and mixed with half an ounce of turpentine, will not only make leather resist wet and damp, but will also render it more durable, pliable, and softer. Warm the boots a little over the stove, and then apply the mixture with a soft brush or swab. Let them dry thoroughly, then paint them over again. Put them in a warm dry place for twenty-four hours, and you will have a pair of perfectly waterproof boots. Still another waterproof composition can be made by dissolving an ounce of powdered resin in a quarter of a pint of linseed oil, over the stove; put it in a tin basin, and place that in a pan of boiling water. When it is boiling hot, slice into it two ounces of mutton tallow, and apply while hot to the boots, letting it dry in thoroughly. The following receipt for making leather waterproof is from authoritative sources, viz., holed oil, one pint beeswax and yellow resin, each two ounces; melt together. Apply warm before the fire.—*Country Gentleman*.

The money loss of champagne by the failure of the Vintage thirty million francs.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE FLOWER GARDEN.

PLANTS CHIEFLY FITTED FOR THE WILD GARDEN.

WHAT first suggested the idea of the wild garden, and even the name to me, was the desire to provide a home for a great number of exotic plants that are unfitted for garden culture in the old sense. Many of these plants have great beauty when in flower and perhaps at other seasons, but they are frequently so free and vigorous in growth that they over-run and destroy all their more delicate and precious neighbours. Many, too, are so coarse and ragged that they are objectionable in choice borders and beds, and after flowering they leave an ugly blank or a mass of unsightly stems. These plants are themselves not only not enjoyable in gardens, but they were the main cause of the abolition of even the mixed border itself, and all its varied beauties, in nearly every garden throughout the land during the past fifteen or twenty years; and yet many of these plants are very beautiful at certain stages. A tall, spreading Harebell, for example, stiffly tied up in a garden border, as has been the fashion up to the present day where plants of this kind have been grown at all, is at best of times an unsightly object;

but the same plant growing amongst the long Grass in a thin wood forms one of the loveliest objects conceivable. The Golden-rods and Michaelmas Daisies again, for example, used to over-run the old mixed border, and were with it abolished. But even the poorest of these seen together in a New England wood in autumn form a beautiful picture. So also there are numerous exotic plants of which the individual flowers may not be so striking as many popular ones, but which, grown in wide spreading groups and seen at some little distance off, afford beautiful aspects of vegetation, and quite new so far as gardens are concerned. When I first thought of the wild garden not one of these plants was in cultivation outside botanic gardens. It was even considered by the best friends of the hardy flower movement a mistake to recommend one of them, for they knew that it was the predominance of these weedy vigorous subjects that made the majority of persons give up hardy flowers entirely for the sake of the glare of bedding plants; therefore, the wild garden in the case of these particular plants opens up to us a new world of infinite and changeful beauty. In it every plant vigorous enough not to require the care of the cultivator or a choice place in the mixed border will find a home. Of such plants there are hundreds in every northern and mountainous country, which travellers may gather and afterwards grow in their own gardens, souvenirs of the pleasant places which they have visited. In this group the common *Acanthus* (*A. mollis*) comes in, though the rarer kinds are fit for a place in any border. The taller *Achilleas*; the beautiful and stately *Aconites*, dangerous in gardens on account of their poisonous roots; the seldom-seen *Acteas*; such *Alliums* as might be admired, and yet, like all their brethren, objectionable from their odour when near at hand; the huge and vigorous, but at certain seasons very handsome, *Altheas*; *Angelica*, with its fine foliage; the herbaceous kinds of *Aralia* from the American woods, also with fine foliage; the Wormwood family (*Artemisia*); the stronger kinds of American Cotton-weed (*Asclepias*); certain of the vigorous species of *Asparagus*; *Asters* and their allies in great variety; the larger and more vigorous species of *Astragalus*; certain of the larger species of *Betonica*, pretty, and with delicate flowers, but hardly fit for the mixed border; various free and vigorous exotic Grasses; large and showy *Bupthalmums*; the handsome creeping *Calystegias*, dangerous weeds in a garden; the most vigorous *Campanulas*; exotic *Thistles* (*Carduus*) and their allies;

the more remarkable kinds of *Carex*; numerous *Centaureas*, somewhat too coarse for the garden; various species of *Clematis* and *Convolvulus*. Others may consist of the coarser growing kinds of—

Coreopsis	Helenium	Mulgedium	Rumex
Crambe	Helianthus	Nepeta	Salvia
Digitalis	Heliopsis	Onopordon	Sanguisorba
Dioscorea	Helleborus	Paeonia	Scolymus

W. R.

WINTER BEDDING WITH EVERGREEN SHRUBS.

THE bare patches of earth which are frequently seen in gardens after the summer occupants are removed, is a somewhat objectionable feature, and one which can only be obviated by having recourse to what is generally termed spring bedding, that is, filling the beds with hardy herbaceous plants, which bloom sooner or later in spring, according to the season, or planting them with dwarf shrubs. The former method is objectionable, on account of the amount of work it entails preparatory to planting, and also owing to the dreary aspect which the plants present during a severe winter, when only the extreme hardy ones can survive, and likewise by this class of plants being invariably at their best when they have to be removed so as to allow of the summer bedding plants to be planted out. On the other hand, when shrubs are employed an immediate effect may be produced, which may be maintained throughout the winter, and will remain unimpaired by frosts. What may be done in this way by a judicious selection and tasteful arrangement has been admirably exemplified by Messrs. Charles Lee & Son, of Hammersmith, who made a much admired display at a recent meeting of the Royal Horticultural Society at South Kensington, and for which they were deservedly awarded a gold medal. This arrangement consisted of parallel beds on either side of the path in the entrance vestibule leading to the Council room, laid out in a series of circles and longitudinal lines. The varied shades of green interspersed with the pretty variegation of many of the plants used formed, on the whole, a harmonious picture, the subdued tones of which presented a striking contrast to the monotonous glare of colour generally seen in geometric designs. The various berry-bearing plants, too, interspersed here and there, such as *Aucubas*, *Spindle-trees*, *Yews*, &c., aided materially in producing an effective combination, and added considerable interest to the display. The rarity of the plants employed consisted chiefly of *Conifers*, and the great variety existing in this class alone would produce an effect by no means to be despised. The feathery pyramids of *Retinospora ericoides* and *plumosa*, the many forms of *Lawson's Cypress*, including the silvery and golden-tinted kinds, the *Arbor-Vitae*, *Junipers*, &c., are all characterised by beauty of form and pleasing tints. The intermixture of standard bushes, varying from 2 ft. to 5 ft., of *Aucubas*, *Ligustrums*, *Yews*, *Ivies*, *Laurustinuses*, &c., gave a diversified aspect to the arrangement, whilst they combined well with the pigmy plants. The edging of one of the beds was of the ordinary English Box, and that of the other consisted of the small-leaved *Spindle-tree* (*Euonymus microphyllus*), which forms a capital substitute. This system of winter bedding has much to recommend it, inasmuch as it gives very little trouble after the plants are once obtained, and they may be afterwards propagated in a simple manner at intervals, as occasion requires, and the facility with which they may be transplanted, and the various uses to which they may be put after they have attained too large a size for bedding purposes, such as forming shrubberies, &c., is no inconsiderable point in favour of the practice.

It is considered inexpedient to reproduce in our columns representations of the arrangement designed on this occasion by Messrs. Lee, as the system may be carried out in any ordinary style of beds, such as are usually seen for summer bedding plants, with equally excellent results; appended is a list of the plants employed in the arrangement at South Kensington, though it by no means exhausts the list of shrubs suitable for the purpose, as there are scores of other subjects which would be equally adapted for such work. On the other hand, such a numerous variety as that here enumerated is not to be considered indispensable, as it is not in the quantity or

great variety of subjects employed, but in their judicious selection and tasteful arrangement, that the appropriateness of this system of bedding consists.

THE KNOTWEEDS. (POLYGONUMS.)

Now that beauty of form is beginning to be appreciated, many plants of graceful proportions that were formerly discarded as worthless, either on account of their gross habit or inconspicuous flowers, are now being brought into notice; and it is more than probable that these will form a prominent feature in the gardens of the future. The vast genus *Polygonum*, which comprises 150 species of world-wide distribution, the majority of which are insignificant weeds, nevertheless includes several noble plants, which claim a consideration that has hitherto been denied them. From an economic point of view they are of little importance, the most useful member of the family being the Buckwheat (*P. Fagopyrum*), which is grown as a bread corn in Eastern Europe and Northern Asia, and as a food for pheasants in this country; some are used as fodder plants, and the tender shoots of others as esculents. They are of the easiest culture, thriving in any ordinary garden soil, but being greatly improved by cultivation. All those of a bushy habit should be so planted as to have a clear space all round, in order to give the foliage all the air and light possible, as overcrowding is frequently the cause of naked stems and a straggling habit, to remedy which tying-in has to be resorted to, a circumstance which detracts much from their natural appearance: their beauty consisting in the innumerable flower spikes rising above a gracefully developed mass of foliage continuous to the ground. Those of the *P. cuspidatum* type, which have few hardy representatives, invariably produce stems of sufficient strength to support their spreading crowns of foliage, though a tendency to droop at the points is not unusual; but this is by no means an objectionable feature. The annuals, unless grown as single specimens, and in sheltered situations, will require support, and the dwarf perennials, most of which are evergreen, need very little attention beyond an occasional trimming. The stems of all the tall hardy species, being of annual duration, die off in the autumn, and the succeeding ones, not appearing before April or May, is a circumstance which must be taken into consideration when planting for effect. Propagation is effected by means of cuttings, division, or seeds, which, if of the *P. orientale* group, should not be sown in the open ground until the middle of April. Several attempts have been made to popularise this class of plants, but through neglecting to keep them within bounds they have fallen into disrepute. To remedy this encroaching propensity, which is their chief drawback, their underground creeping rhizomes require to be cut back every spring. The selection described below includes most of the best sorts for garden purposes, and illustrates the various types of the genus.

P. alpinum.—A native of the Swiss Alps, and a very old inhabitant of our gardens. Its stems attain the height of 3 ft. to 4 ft., with ovate-lanceolate deep green leaves, with ciliated margins. Its flowers, which appear early and continue in bloom for several weeks, are arranged in snow-white panicles, and prove very serviceable where quantities of cut flowers are in request.

P. amplexicaule.—This usually reaches the height of 4 ft. to 5 ft. Its stems are rather slender, but well furnished with stem-clasping, cordate-lanceolate leaves, with deeply-veined surfaces and tapering points. Its slender flower-spikes, which rise a foot or more above the main body of the foliage, are of a rich pure crimson, an uncommon colour among herbaceous plants. A variety of this named *oxyphyllum* differs from the type in having white flowers with conspicuous red anthers. Both the species and the type are natives of the Himalayas, a region in which the genus is well represented.

P. cuspidatum, also known as *P. Sieboldi*, is a plant of sterling merit, now becoming quite common, belonging to a section with a semi-arborescent habit, and a peculiar curve of the stem, which brings nearly the whole of the foliage of each spray into the same plane. Its shoots are copious, speckled with purple; its broadly-ovate leaves, which are of a dark dull green, are frequently variegated with faint silvery blotches, and its creamy-white flowers are borne in great profusion. Its stately habit of growth, combined with the luxuriance of its foliage, are attractions of no ordinary character, which cannot fail to strike the most casual observer, and especially when in full bloom. A native of Japan, and is undoubtedly one of the finest herbaceous plants in cultivation. To do it justice it should be grown as an isolated specimen, either on the turf or in some prominent position of the wild garden, as represented in the annexed figure. The variety *compactum* is a distinct dwarf form with crowded foliage and flowers, and is more suitable for the herbaceous border or for pot culture.

P. sachalinense.—A native of the Island of Sachalian, and of a similar habit to the preceding, but of much larger proportions, often attaining the height of 10 ft. to 12 ft., with broadly-oblong leaves upwards of a foot in length, which are of a bright green. Its flowers are rather inconspicuous, being of a greenish-white, and disposed in slender drooping racemes. It luxuriates in a moist subsoil, near the margin of water, where it is very effective in company with grassy vegetation. It also makes a fine bold feature, either planted on the turf or in a good position where it can develop its noble proportions. No better plant could be employed for naturalisation in semi-wild places.

P. polysachyum.—This forms a thicket of stout, erect stems, which root strongly from the first few joints above the ground. Its leaves, which are somewhat crowded, are elliptic-acute in form, with a furrowed midrib, and a light coloured under-surface. It reaches the height of 5 ft. to 6 ft., including the flower-spikes, which are slender and greenish. The qualities that recommend it are its bold, erect habit, and dense, woolly foliage. Also an Himalayan species.

P. ribesoides.—This is a climbing plant, which would answer well for covering trellis work, pillars, and arbours. Its reddish, twining stems give off at intervals of 2 in. or 3 in. bright green sagittate leaves with short pink stalks. Its flowers, which are produced in the axils of the upper leaves towards autumn, are borne in racemose panicles of a creamy-white colour. No better substitute could be found for the *Boussingaultia* than this, and it has the advantage of blooming freely in the open air.

P. filiforme.—A very hairy plant, some 3 ft. to 5 ft. in height, with broadly-ovate, acute, short, downy leaves, with prominent ribs below. The flowers are small, and arranged in slender greenish spikes. The golden striped form of this plant has few equals among variegated herbaceous plants.

P. Brunonis.—Of the known evergreen species this is probably the best, leaving out *P. vaccinifolium*. Its leaves, which are spatulate, with a white under-surface, are mostly radical, and so numerous as to form a dense cushion, from which arise the numerous crimson spikes. It is an extremely pretty border plant, and a native of the Himalayas. It comes near to *P. Bistorta*, a British plant known as the Snake-root, well worth growing for its rich green foliage and red flower-spikes.

P. vaccinifolium.—Few plants surpass this for rockwork. It differs widely from all its congeners at present in cultivation, unless *P. crispum*, once a favourite flower, is still to be found in gardens, which resembles it in its twiggy habit. It is quite hardy, and thrives in almost any moist soil, and is seen to the best advantage where its shoots can ramble over stones or tree stumps. Under favourable conditions it grows rapidly, and produces its Whortleberry-like leaves and rosy flower-spikes in profusion. This is also a native of the Himalayas.

P. capitatum.—This is a charming little annual of a spreading habit, with oval greyish-green leaves, with a dark blotch in the centre of each, and numerous globose heads of pink flowers. When once established in light warm soils, it appears every year from self-sown seeds. Its neat habit, combined with the delicacy of its flowers, are qualities which never fail to attract admirers.

P. amphibium.—As its name implies, it is both a dry land

plant and a floating aquatic. In its terrestrial state it is not very attractive; its leaves are somewhat lanceolate, and nearly sessile; but, when it changes to an aquatic, it assumes a very different aspect; its leaves become long-stalked with oblong flat blades similar to those of the Cape Pond-weed (*Aponogeton*), but, instead of the forked inflorescence of that plant, its flowers are disposed in long cylindrical spikes, which rise several inches above the bright green floating leaves, and have a remarkable showy appearance. Of the twelve British species, this and *P. Bistorta* are the only ones of any horticultural value.

P. orientale.—A gigantic free-growing annual, growing to the height of 8 ft. to 10 ft. Its stems are very robust, and give off numerous lateral shoots, which are supplied with large, oblong, acute, rich green leaves, measuring 10 in. to 15 in. in length, of which those nearest the flowers are stem-clasping, and more inclined to be sagittate. The inflorescence is both terminal and axillary, and consists of slender spikes of crimson flowers, which make their appearance in July, and continue until the frosts. To obtain a good development of its foliage, it should be grown as a single specimen and without shade to induce it to bloom freely, when it makes one of the grandest of ornaments, either for the sub-tropical garden or for some conspicuous place among its congeners in the wild garden. There is a variety of this with pure white flowers, though both are rarely met with. It is a native of Northern India.

P. Fagopyrum.—This yields the Buckwheat, the triangular black husks of which are used so extensively for packing dry bulbs. Like the foregoing, it is a stately annual, but varying in height from 3 ft. to 7 ft. In habit the plant is more slender than the preceding, with fewer and more erect branches. Its leaves, which are very ornamental, are either cordate or sagittate, and, in some of the varieties, with red veins and foot-stalks. The flowers vary as much as from white to red on the same plant, though some varieties have pure white flowers. This species, which is grown largely by the natives of Northern India, appears to be quite as variable as our cultivated grain plants. Well-grown specimens of any of the varieties are very effective with their panicles of variegated flowers and delicate green foliage.—C. M.

The Great Japan Knotweed (*Polygonum cuspidatum*).
(Showing the part of the plant in flower.)

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Cyclamen neapolitanum.—The fine weather which we have lately been experiencing in addition to bringing out a bright display of ordinary summer flowers, has greatly favoured the development of the hardy flowers that usually cheer the dreary month of November, and among these few are more welcome than the hardy *Cyclamen neapolitanum* that is now flowering freely in open borders. We have some large bulbs of it, probably many years old, planted under the partial shade of *Yuccas*, hardy Palms, &c., in a well sheltered border, and their beautiful tufts of mottled foliage and profusion of pretty flowers give the garden more of the aspect of spring than that of the near approach of the winter.—J. GROOM, *Linton*.

Cistuses or Rock Roses.—Mr. R. Potter points out (p. 431) the difference between *Cistus ladaniferus* and *C. cyrius*. I am well aware of this, and of the superior beauty of the first-named species. I should therefore be greatly obliged to Mr. Potter or any other of your correspondents if they would inform me where I could procure the true plant. I have made many unsuccessful attempts to get it, and I fear that it is not now common in the trade. On more than one occasion I have had *C. cyrius* sent to me for the true *C. ladaniferus*, and I believe that many cultivators are not aware of the difference.—J. D. LLEWELYN, *Atherton Grange, Wimbledon*.

Marigolds.—To thousands of cultivators whose means are scanty and space limited, half-a-dozen plants producing a few flowers now without heat are worth ten times as many at midsummer, when the garden is ablaze with colour. Just one such plant is found in the new and very pretty pot Marigold Meteor, plants of which, raised from seed last July, I saw in pots the other day in a cold house. At this dull time their bright lemon and orange striped handsome flowers are a most grateful sight. This is a plant which must soon become a favourite.—D.

Hose-in-Hose Primroses.—The improvement going on of late in the single hardy Primrose has now resulted in a charming and perfect Hose-in-Hose variety of a clear yellow colour. Hose-in-Hose Polyanthus have been in existence for a long time, but in Primroses it is a novelty. These duplex forms are not merely curious as showing a process of natural development entirely due to careful selection on the part of the florist, but they also furnish a greater amount of colour than could be obtained in the case of single flowers. Any one who has seen a mass of some of the white or yellow duplex Polyanthus in bloom in spring will, I am sure, freely admit that in colouring effect they are far in advance of the single flowered kinds.—A. D.

Gypsophila paniculata.—To those who, like myself, have the misfortune to reside in northern latitudes, the description (p. 411) of such lovely spots as St. John's Vicarage, Ryde, is very interesting. In "Delta's" description of the varieties seen in the

garden in question is the following: "Gypsophila paniculata, a most delightful subject for nosegays, I have never been able to manage, and was told the secret was to grow it in peat." Will "Delta" kindly inform us what the above plant is? Surely it cannot be the old Gypsophila which he says he could not manage; if so, I am afraid he would find it difficult to manage an Oak tree, with which the enormous root stock of this truly hardy plant has some affinity, an old-established plant being a thing to test a spade in lifting it. Then there is the grand secret "to grow it in peat;" recommend a chalk-loving plant to be grown in peat! Why, the very name "Gypson," chalk, and "phileo," to love, points to the contrary. The very structure of the plant seems to point to its home among mountain

rocks, from its almost aerial gracefulness of bloom. I have heard it called the spirit plant. It possesses no qualities to make it a bouquet plant, but, like the *Statice*, it makes a capital plant in a dried state for grates, epergnes, and similar purposes. I am treating of *Gypsophila paniculata*; perhaps "Delta" will kindly enlighten us on the matter.—THOS. WILLIAMS, *Ormskirk*.

Thrips.—Nelson ascribed his victories to "always being a quarter of an hour before his time;" and this habit of forestalling enemies is a very desirable one for cultivators to follow, especially when dealing with those troublesome insects called thrips. One may neglect scale and bug for a few days with no other immediate result than an increase in their numbers; but to let thrips get the upper hand means destruction to the foliage, and a lowering of the vitality of the plant. These little matters require to be looked after now, when fires are necessary in plant-houses. Tobacco fumigation is the best remedy, to be followed up in bad cases on alternate evenings till three fumigations have been given.

Orchards.—In travelling some hundreds of miles through England by rail I observed many orchards—old orchards—but scarcely a single plantation of young fruit trees was seen. This is instructive and shows that people trust too much to gnarled and decrepid old standard trees. Many well-planted new plantations should be made if ever home-grown fruit is to be plentiful—good sorts on good soil; and a general system of planting on the part of landed proprietors,

of cultivators sure of their tenure, is of all things to be recommended now that corn-growing and meat-producing are failing us.—B.

TREES, SHRUBS, AND WOODLANDS.

THE GROWTH OF COPPICING.

In many parts of the country, upon soils which will not grow the ordinary timber trees of sufficient size to make their cultivation profitable, coppicing may be substituted with advantage, and the annual income to be derived from this will, under proper management, be little less than that obtained from the periodical falls of timber upon superior soils. But in order to ensure the maximum of profit from such, the species grown must be such as are suitable to the land, and also those for which there is a local demand. Thus in Kent, Sussex, Herefordshire, and Worcestershire, Hop-poles meet with a ready sale; in the mining districts, pit-props; in hardware districts and in the potteries, material for making crates; and in the basket-making localities, Willows of various kinds. The subject of local demand is an important one, as compared with their market value the materials obtained from ordinary coppices are too bulky to admit of long carriage either by road or rail.

Pure coppice of the best kinds, such as Ash, Spanish Chestnut, Red Willow, Red Birch, and Maple, are in the Hop-growing counties more remunerative than coppice with standards; but where the underwood is of an inferior kind, such as Oak, Beech, Hornbeam, Hazel, and the common kinds of Willow, a considerable admixture of standard trees may be reared with advantage. But under ordinary circumstances these should not occupy more than one-third of the wooded area, and their lower branches should, after every fall, be either pruned back close to the boles, or else considerably shortened to mitigate the effects of too much shade. Most of our common deciduous trees coppice freely—the Ash, Oak, Spanish Chestnut, Elm, Lime, Maple, Poplar, Willow, Hornbeam, Birch, Mountain Ash, Sycamore, Hazel, Alder, and, for a shorter period, the Beech. Some of these, such as the Lime, Willow, the Aspen Birch, and the white Alder, grow very freely from suckers. For pure coppicing the Spanish Chestnut is best adapted to sandy or gravelly land, Ash for a moist loamy soil, and Larch upon rocky slopes; upon a moist loamy or clay soil Chestnut stools very soon die out, and upon a deep good soil Larch grows too rapidly to be very serviceable.

By means of planting and subsequent layering, growths of coppicing may be carried over rocky surfaces where timber trees even of the smallest size are reared with difficulty, for as long as its connection with the parent stool is maintained, the layer will continue to thrive, even though its roots obtain little nourishment beyond what they find in the thinnest surface soil or among the crevices of the rocks.

The length of a rotation will depend to a great extent upon the kind of wood grown, and the purposes to which the produce is to be applied, as well as upon the climate, site, and quality of the soil. The shorter the rotation, the sooner the stool is exhausted. When Osiers receive an annual cutting, the stools seldom last more than 13 or 14 years; though those worked upon a two or three years rotation endure for nearly double that period. Standard trees cut down after the age of from 40 to 50 years, seldom leave a reproductive stool, though instances have been recorded in which they have shot up afresh even when more than a century old. But with good management and careful cutting, a Chestnut plantation may last for more than 150 years. From nine to thirteen years is the common length of a rotation, but basket-makers' Osiers are cut at the end of the first and second years; Hazel for crates and hampers and for the coopers' use, at the end of the third; Ash and Spanish Chestnut upon good soils, at the end of the ninth or tenth years; and Oak, Hornbeam, Birch, &c., upon inferior soils, at about thirteen years old.

As coppice shoots are produced either by the adventitious buds which spring from the edge of the cut surface of the stool, or from the dormant or lateral buds which proceed directly from the medullary processes in the wood, and below the former, the method of cutting has a considerable influence upon the future crop. When the bark is torn from the edge of the stool's surface, the adventitious buds are destroyed, and heavy blows from a blunt instrument will also destroy the dormant buds, and even break off the finer fibres of the small stools standing in loose soils. To avoid this, the poles growing upon the smaller stools should always be cut off with the bill-hook, and everything under 6 in. in diameter with a light axe. All tools used in coppice felling should be of the best kind, and also be kept to a keen edge. No cutting should be permitted during frosts, and all blows should be directed upwards as far as practicable. Except in very wet situations, where the stools are occasionally partially immersed, they are best cut off as close to the ground as possible, in which case the dormant buds send up shoots from near the surface

of the ground, or even below it, and these, in time, become well rooted in the soil, and at the next cutting considerably extend the area of the stool.

To produce a luxuriant crop of young shoots the best time of cutting is between the middle of February and the end of March. But in most districts the work goes on from early in November until the beginning of April. Where a large breadth has to be cleared by the same hands, the younger plantations should be cut first.

A. J. BURROWS.

THE FORESTS OF THE NORTH.

In addition to the Fir and Pine, which, of course, form the bulk of Norwegian forest growth, there is the Birch (*Betula odorata*), which in West Finmark is found in considerable tracts, and occasionally in other parts of the country, amongst the clearings of the Pine and Fir woods. The limit of elevation, as far as its geographical distribution goes, is about 1,101 mètres (1 mètré = 1 1-10th yard) in Southern Norway, 600 to 700 mètres in Trondhjem district, and from 300 to 400 in Finmark. It is a pretty and well-grown tree, is frequently met with growing to the height of 60 ft. to 70 ft., and with a diameter of 3 ft. or 4 ft. at the base. A good deal of Birch wood is used as fuel, but it is a useful wood for cabinet makers, and its outer bark is of value in many industrial occupations. The Birch tree adds much to the scenic effects of the forest, with its long drooping cluster of branches, and is one of the most characteristic ornaments to a Norwegian valley. Some of the Birch groups, indeed, have quite a celebrity throughout the country for their beauty, and not only their owners, but the whole of the population of the district regard them with pride, naming them according to their fancy. There is a magnificent specimen of Birch called the "Holsbirk" on the property of Hol, in Rennebu, in the prefecture of Southern Trondhjem. It is 68 ft. in height, and has a diameter of 5 ft. at 4 ft. above the ground. Any sacrilegious person who attempted to destroy or damage "Holsbirk" would have a bad time of it amongst the peasantry of the neighbourhood.

The other trees which help to make up a Norwegian forest will not need much description. The Alder (*Alnus incana*) is found at about the same limit of growth as the Birch, and is met with pretty frequently as far north as West Finmark, attaining a height of about 60 ft., with a diameter averaging 1 ft. The variety of Alder known as *Alnus glutinosa* is very much scarcer, and is principally found in the valleys by the side of the streams, where the ground is rather damp. It is never seen above the height of 250 to 300 mètres. The Beech (*Fagus sylvatica*) never grows wild beyond 61° lat., but when planted and looked after, it is found as far north as 69°, at Stegen in Nordland, and also at Trondhjem (63° 26'), where it does very well. In the sixtieth degree of latitude it forms small forest groups at Tonsberg, Larvik, and Arendal, and further north at Bergen and Saem. This is probably the most northerly wild Birch wood in the world. There are two varieties of Oaks that grow in Norway, those with sessile glands and the pedunculated Oaks, the latter in small forest groups on the coast between Arendal and Flekkefjord. It ascends as far north as 63° in a wild state, but when planted flourishes at 66°. The Hazel (*Corylus Avellana*) grows wild on the low grounds to the south of Trondhjemfjord, but north of that it is rare, though occasionally found as far as Stegen (68'), where its fruit ripens. The Elm (*Ulmus montana*) is met with up to 67°, but, as a rule, never at an elevation higher than 500 to 600 mètres above the sea. It is an isolated tree, growing to 90 ft. or more; and the only example of an Elm wood is at Solvorn, near one of the inland arms of the Sognefjord.

The Willow (*Salix caprea*) has a much more extensive range, and is found even above the limits of the growth of the Fir, as far north as Hammerfest (70° 37'), though only in the condition of bushes. But at Alten in Finmark (70°) it attains the height of 26 ft., and 1 ft. 3 in. in diameter. The Poplar (*Populus tremula*) has an equally wide range, and in the southern parts of Norway is met with, though in rather a stunted growth, at the height of 900 mètres above the sea. But while in the low country it is 60 ft. high, it is little more than half that at Alten (70°). The Ash (*Fraxinus excelsior*), when wild, is not found further north than Molde in Romsdaal (62° 44'), but as a cultivated tree it flourishes even as far as the polar circle. The Lime (*Tilia parvifolia*) has a somewhat higher range (62°) on the west coast to what it has on the eastern border, where it is one degree less. Cultivated, however, it reaches as far as Stegen (67° 56'). The Mountain Ash (*Sorbus Aucuparia*) is common throughout the whole of Norway, and in ordinary summers it ripens well. With its pretty bunches of red berries, which attract multitudes of birds, it gives great colour and warmth to the hill-sides in winter.

Amongst the smaller class of trees which flourish in Norway may be mentioned the Juniper (*Juniperus communis*), generally met with

as a shrub, but occasionally, as at Selbo, in South Trondhjem, attaining the dignity and proportions of a small tree 36 ft. high. It grows everywhere, even as far as the North Cape, exceeding the Birch in this respect; but it requires a dry and the poorest of soils. Of Osiers, there are nearly twenty varieties in Norway, as wild shrubs, growing at a considerable elevation on the mountains, and especially in a damp, boggy locality. The wild Apple (*Pyrus Malus*) is met with every here and there as far north as the island of Yterö in Trondhjemfiord (63° 49'), though never more than 500 metres above the sea. There are two varieties of wild Cherry tree (*Prunus Avium* and *P. Padus*), the former rather localised, and found principally in small woods at the head of the Sognefiord, while the latter is much more common and has a wider range, ripening as far north as Tanaels, in East Finmark (70° 20'). Besides these are the Sloe (*Prunus spinosa*), growing up to 60°; the Barberry (*Berberis vulgaris*), which extends 4° farther north; the wild Currants (*Ribes Grossularia* and *R. rubrum*), the latter flourishing under the same conditions and limit as the Fir; the wild Raspberry (*Rubus Idaeus*), very common as far north as Finmark; and the Blackberry, the only wild fruit in Norway, which is looked upon as a property, and which in Tromsö and Finmark is a source of some considerable revenue. Although not coming under the denomination of timber, it is fair to mention the numerous varieties of Bilberry or Whortleberry, and of Cranberry (*Vaccinium*), which grow in great abundance, and form such an agreeable addition to our culinary resources.

Bailler.

Berberidopsis coralina.

Amongst all the interesting and handsome shrubs which we have obtained from Chili, few, if any, surpass this in real beauty. It is of scandent habit, has glabrous, evergreen, spiny leaves, and long-stalked, deep crimson blossoms, which last a long time in beauty, and which are, moreover, produced in succession over a long period. It succeeds well in good fibrous loam, with a slight admixture of peat; and here in Newry it has proved quite hardy in various positions, such as against a due south wall, on a western aspect, and also hanging over and creeping amongst stones or rockwork; in open situations, too, fully exposed all round, it succeeds about equally well. I am not aware how high it will grow ultimately and under very favourable conditions, but my opinion

is that it will not much exceed 3 ft. in height, seeming to have rather a tendency to extend laterally than upwards. Therefore, its proper position on a wall would be one of those bare spaces which one often sees between two other wall shrubs that grow wide at the top and leave the base bare. It is one of those really good shrubs for which place should be made in every garden.—T. SMITH.

Trees in Streets.—The new street called Fitzjohn's Avenue, half a mile long, and between 50 ft. and 60 ft. broad, which connects Hampstead with the Swiss Cottage, is being planted on either side with Chestnut trees, alternately pink and white. The cost, estimated at £200, will be defrayed by the residents of this suburb, Sir Spenser Wilson having already contributed £100. Fellows Road is also being planted with Plane trees, and the altered portions of Well Walk with Limes.

Shelter and Shade.—Shelter in winter and shade in summer are important points for consideration. Evergreen trees and such deciduous ones as retain their foliage until a late period of the year—the Hornbeam, Beech, and some varieties of the Oak—afford

much greater shelter in winter and the early spring, when it is most required, than those which lose their leaves early in autumn, and these should be planted wherever shelter is desired. Shade is best afforded by trees which rise with naked stems to a considerable height, and then send out a profusion of branches, as the Oak, Beech, Chestnut, and Elm, which can be readily trained by a little pruning, and their spreading branches and umbrageous foliage are greatly superior for this purpose to the Ash, Sycamore, and Plane.—B.

Distribution of Trees.—Humboldt tells us that the trees which occupy the highest elevations are the Pine and the Birch. The highest altitude at which the Pine grows is 12,000 ft. to 15,000 ft. above the sea level in latitude 20°, and the limits of the growth of the Oak appear to be about 10,300 ft. In Mount Caucasus the trees found nearest the limits of perpetual snow in latitude 42½°, and also on the Pyrenees, are the common Birch (*Betula alba*) and the hooked Pine (*Pinus uncinata*), as well as the red Spruce Fir (*Pinus rubra*). On the Alps, in latitudes from 45° to 46°, the common Spruce appears limited to an elevation of about 5,900 ft. In Lapland the Birch is found at an altitude of 1,600 ft. in latitudes from 67° to 70°.—A. J. B.

Planting Trees in Masses of the Same Variety.—The late Lord Chief Commissioner Adam first adopted this method of planting forest trees on his estate at Blair Adam, and though this was afterwards changed to the mixed system of planting, he afterwards returned to the original method, more especially upon the hill-sides. The reasons he assigned for this were that for purposes of embellishment the larger masses of different colours, especially on the slopes of the hills, produced more effect in point of grandeur than an intermixture, the latter being better adapted to the woodlands near the residence and to the pleasure grounds. He also found from experience that, during the process of thinning, the forester frequently left trees of inferior value, because from their greater rapidity of growth they had become the most showy, whereas in masses of the same kind the most valuable trees were generally left to grow on.—A.

Mistletoe.—In Hereford and other Apple-growing counties considerable trouble and expense are annually incurred in ridding the pest of Mistletoe

from the trees. Some people turn curses into blessings, and so we find Mr. Smith, of Worcester, does, by inducing Mistletoe to establish itself on fine young Apple trees, which are then sold at prices varying from 7s. to one guinea each.—B.

Euonymus linifolius.—All *Euonymus*es are not remarkable for their scarlet fruit, although in most cases this fruit furnishes a distinguishing characteristic. To the former class belongs *Euonymus linifolius*. The excellence of this shrub lies almost entirely in the beauty of its leaves, which are small, narrow, and of a dark colour. Slower growing than most *Euonymus*es, it is best fitted for the front ranks of shrub groups. The narrow leaves have a wavy appearance, which increases the effect of the otherwise strongly marked qualities. I like to note the attractions of such shrubs as the *Euonymus linifolius*, for the special reason that they afford a striking instance of diversity of appearance in a species of shrubs generally considered little capable of variation in their deciduous forms.

Berberidopsis coralina.
(Sketched in Messrs. Veitch's Nursery, Coombe Wood.)

THE FRUIT GARDEN.

THE MATURATION OF FRUITS.

FREQUENT correspondence on this subject induces me to offer a few remarks concerning it. Judging from what is practised and written on the subject of ripening Melons, forced Strawberries, and Pine-apples, &c., it appears to be a very generally accepted idea among fruit growers that some kinds of fruits are improved in quality by being subjected to a kind of starvation process, induced by withholding moisture to an excessive degree just at the critical period when the fruit is perfecting its juices and attaining its highest degree of perfection. In conformity with this idea, it is quite a common thing for cultivators to allow forced Strawberries to droop for want of water at the root when the fruit is approaching maturity; to roast Pines in a temperature almost as high and as dry as an oven, when the fruit is about to colour; and to parch Melons to such an extent as actually to deprive them of their foliage before the fruit is ripe—aye, even to kill the plants themselves when they have only reached the age of fertility; for we know that the Melon is capable of bearing several crops in succession when properly managed—a thing quite out of the question in the case of plants that are “dried off” at the end of the first crop.

Not long since, a writer on Melons stated, as a guarantee of the good quality of this fruit, that by the time it was ripe the foliage was quite withered, thus securing only one crop of four or five fruits to a plant, after all the labour of making up forcing beds, &c. On the other hand, numbers of good Melon growers take four and five crops in succession from their plants, and fruit of the highest quality, by preserving the foliage in good health as long as possible. The writer, was often told, when a learner, that the dying off process improved the quality of the fruit; but the results never proved as much, in any case he can remember. Indeed, such practises are quite opposed to all physiological knowledge on the subject, and their utility is contradicted by experience. One cannot imagine what excuse can be set up for subjecting plants to a course of treatment that arrests their proper functions more or less, and saps the very foundations of life itself, if continued for but a brief period. Surely, such treatment cannot impart any desirable quality to the fruit! Acting on these convictions, I have invariably watered the plants up till the time the fruit was quite ripe, just as at other times—and that was sufficiently to maintain the foliage in good health, and prevent it suffering from drought, even in the slightest degree.

In the case of Vines and Peaches, &c., I suppose no one will deny that the parching system is wrong; why, then, is an exception made in the case of Melons, Strawberries, Pines, and such like? In the case of the latter it is a common practice to withhold water altogether from the plants when they are about beginning to colour, and some withhold it sooner, with the object of hastening maturity; but the practice is wrong. With winter-ripened fruit, when the pots are plunged in moist tan, it does not matter so much; but summer Pines grown in pots above hot-water pipes will not stand it without injury. I always watered these up till the day they were cut, just the same as at other times, and in cases when I have had a lot of Queens standing in pots in the fruit room for a long time, I have watered the roots occasionally, in order to preserve that degree of plumpness and finish that they had attained. Neither do I consider it a wise practice to cut Pines while yet half ripe, and hang them up in a dry room, to let them finish in that condition. The fruit will acquire a dull yellow colour, it is true, but both flavour and weight are greatly impaired thereby, nor does the fruit keep much longer in good condition than it does if cut ripe; and it is certain that when the plants are moved with the ripe fruit upon them to a cool house, they will keep as long as is often necessary. As to pot Strawberries, the fruit is always best—most solid-fleshed and best in flavour—when gathered from plants that have always had sufficient water to keep the leaves not only from drooping, but green and luxuriant to the end. The plants are much improved by being removed to any airy and dry structure when about finishing their crop; but water should not be withheld from the roots while any fruit remains to be gathered.

In the case of Melons, it is, however, well to consider how the plants are grown in determining the quantity of water to give them about the ripening period. Old cultivators, who had to grow their crops in manure frames, tell us that they used to cease watering the bed entirely after the fruit was set, and that the plants usually finished their fruit in fine condition. This any one can easily believe who knows how long a manure bed, perhaps 2 ft. or 3 ft. deep, will keep in a moist condition. In such circumstances the plants are not drawing their nourishment from the surface of the bed to any great extent, but deep down from the manure heap, which also keeps the soil bed above pretty uniformly moist. It is quite different, however, when bottom heat is derived from hot-water pipes, as is fre-

quently the case now; and it is this which makes Melon growing under the two systems so different, and necessitates such opposite treatment. Above hot pipes the bed is always parting with its moisture, and never receiving any, except from the watering pot; and experience shows often enough that, when water is withheld for a short time, the comparatively thin and narrow bed of loam gets as dry as dust, and, as a rule, more so at the bottom near the drainage, where the great bulk of the feeding roots have penetrated—a thing which often happens through timid watering at other times as well. Consequently, when a Melon plant is deprived of the usual supply of moisture at the ripening period, it may easily be guessed what is likely to happen. The foliage droops and withers, and at the same time the fruit changes colour and ripens prematurely, and is inferior in flavour, and only in a less degree than a fruit that has been cut from the plant altogether when about changing and ripened on the shelf. Such fruits are seldom eatable. None of these evils need happen, however, if water is furnished to the roots as required; and there is no doubt about the fact of several good crops having been taken in succession from plants so circumstanced. In short, Melons, Pines, and Strawberries, and similar fruits should be supplied with water up till the time they become fit for the dessert. J. S. W.

ALLOTMENT ORCHARDS.

THAT the allotment system of gardening, so generally extended some forty-five years ago or thereabouts, greatly benefited the labouring classes no one, I suppose doubts. It is stated to have diminished crime among the peasantry, and generally to have improved and elevated their character. Allotment sections are very numerous in the great industrial districts throughout Yorkshire and Lancashire, and elsewhere; they are perhaps most numerous and best cultivated near towns and large factory colliery villages; for the agricultural labourer is by no means the best gardener, the artisan or the collier, who is confined to the shop or the pit during the week being, if anything his superior in that respect. As a rule, however, allotments are exceedingly well cultivated, and great emulation is displayed by the different occupiers. This, indeed, is one of the advantages of the allotment system. The gardens or plots all lying together, each witnesses daily the results of his neighbour's industry and skill, and is encouraged to follow his example; and it is quite gratifying to see the skill and industry displayed by these gardeners, and what they accomplish. Those who have large families, as a rule, go in for useful vegetables—such as Potatoes, Carrots, Onions, Beans, Peas, and greens, &c.—and the examples of culture which they produce are quite equal to what are usually seen in gardens of greater pretensions. Others cultivate flowers, and some make a hobby of Roses, in which they do a lucrative trade; while some of the most industrious and persevering own a greenhouse or a Cucumber pit, and make both pay as well as any market gardener does.

As good an example of this kind of gardening as could be seen anywhere, perhaps, is at Doncaster. The allotments are situated a short distance from the town, and belong mostly to the mechanics and artisans connected with the Great Northern Railway Locomotive Works there, where some thousands of hands are employed. The gardens are laid out on a fertile piece of land, and most of them are neatly hedged off or divided by a fence of some kind. A missing feature, however, in all such instances is the culture of fruit on a remunerative or even useful scale. Strawberries are often grown, and very successfully, and, to a certain extent, also Gooseberries and Currants; but Apples, Pears, and Plums are scarce, and when a few trees are planted they are often chance sorts, of no great value to the cultivator. The Victoria Plum, the best recognised kind, is sometimes grown with profit. It cannot be doubted for a moment that fruit culture would be very popular amongst allotment gardeners; but the system does not permit of its development on a thoroughly practical scale. The holdings are, as a rule, small, and in most cases, if cropped with Potatoes alone, they would not produce more than would supply a family of five or six. Fruit growing, is therefore, necessarily restricted. Garden stock generally consists of Potatoes, Cabbages, Onions, Celery, Lettuce, Beans, Peas, and Runners, and perhaps a few small fruit bushes. Big trees in such small patches are out of the question, as they soon shade the ground, interfere with the cropping arrangements, and are objected to by the occupiers themselves as boundary lines for obvious reasons.

I am acquainted with extensive allotments that contain hardly a single fruit tree. Yet land and horticultural societies and land-owners can, if they like, do as much for the culture of fruit among the poorer classes as has been done for cottage gardening generally by the allotment system, and this by simply applying the same system to the culture of fruit—in other words, by establishing “allotment orchards,” planted with really good and suitable varie-

ties of Apples and Pears, Plums, and Cherries, &c. There are no difficulties in the way of such a scheme that we are aware of, and it would be one way of giving a direct and general impetus to the culture of fruit in this country—a thing so much desired and written about. In these times of depression in agriculture the landlord could let his ground for such purposes at a figure considerably above farming prices, and still at what would be but a comparatively nominal figure to the tenant. An allotment fruit garden for one family need hardly be more extensive than a vegetable garden. A piece of ground that would hold a dozen or two dozen trees at the most would be sufficient in the majority of cases, and less would satisfy many. It would be desirable to prohibit the cropping of the ground with vegetables generally, as that would only tend to defeat the purpose in view: but there would be no objections to cropping between the larger trees with Strawberries and other small fruits, which, if properly managed, and as they could be at exceedingly little cost, would be as remunerative as anything else. It is doubtful, however, if it would be worth while to recommend any artificial system of training the trees in allotment gardening. Such attempts are more likely to result in failure than anything else, except in experienced hands; but ordinary orchard trees, we know, do thrive and bear well without any particular care.

What can be done in the culture of fruit trees by cottagers is often enough exemplified in isolated cases. I know cottagers possessing a few Apple or Pear trees of good sorts that annually make a considerable sum of money by disposing of the fruit to the nearest fruiterer, who gathers it and takes it away himself. Nor need our periodical losses of crops through bad seasons discourage anyone. Bad as the present season has been, the crops of all small fruits have been in most cases abundant, and we know that our scarcity of Apples and Pears, &c., in unfruitful years is as much due in individual cases, to the kinds planted as anything else. Market gardeners seem best to realise the necessity of planting sorts suitable to the locality, or which are at the season good for market purposes. In establishing an allotment fruit garden, it would be advisable for its promoters to exercise some jurisdiction in this respect, as cottagers are usually but ill-informed on such matters. In conclusion it may just be remarked that the situation selected for allotment gardens is too often a very unsuitable one, both as regards shelter and soil. An exposed field, open to the highway, for example, is far from suitable. On gentlemen's estates this matter is generally considered, and it is seldom a tolerable site could not be chosen in any instance; but in too many cases it is not the interest of the gardeners that is considered, but the convenience and pleasure of the owner of the land, who consents to let a portion of it that is of the least value to himself. I think the time has come when the allotment system of gardening among the working classes might receive a little more attention from those who profess to be interested in the subject of extending fruit and vegetable culture in this country. The allotment system, if properly directed, presents facilities for the extension of both in a way that no other plan yet suggested does.

C.

GRAPES WITH AND WITHOUT FIRE-HEAT.

THE idea of growing Grapes without the aid of fire-heat has an attraction for many small cultivators and others who are desirous of growing their fruit as cheaply as possible, and it would not be wise to discourage attempts in that direction; but it may be worth while to inquire how far anything like constant success in the way of crops of well-ripened fruits is likely to attend such a practise. It is desirable, for more reasons than one, that as little fire-heat be employed as possible in Vine culture; but were I about to grow Grapes, either for my own use or for the market in this country, and had to build Vineries for that purpose, I should provide means for heating them as well, and also employ the same during some part of the growing season. I do not believe in growing Grapes in cool houses; but, at the same time, would not seek to dissuade any one from utilising such structures as greenhouses or cool pits for Vines when opportunity offered. I am, however, almost inclined to think that Grape culture on open but heated walls where the climate was in any degree favourable would be preferable in such places. When Grape growing is a question of profit and loss, the item of hot-water pipes, in first outlay, and fuel afterwards, will not be felt nor grudged. I can safely say that with us the cost of coal, expended in heating the Vineries here, is but a fraction compared with the value of the crops, and I have not the least hesitation in saying that culture with the aid of fire-heat, when necessary, for summer and autumn crops, or such as may be supposed to be grown "without fire-heat," is by far the most remunerative, and that even where coals cost more than they do with us. And that being so, I think, disposes of the question as to which plan is the best. The most miserable failures in Grape growing I ever saw were in cool houses,

or houses that could not be heated sufficiently for the Vines. I remember a noted London nurseryman attempting to grow Grapes in a large show conservatory. The Vines were well cared for by qualified gardeners—trained and thinned in the usual way; but mildew appeared, and completely ruined the crop. The sight, when the writer saw the house in question, was enough to give an enthusiastic Grape-grower the nightmare. It is mildew, poor flavour, and the danger of the Grapes never attaining maturity that is most to be feared.

In ordinary fair seasons, Black Hamburgh Grapes may be ripened in cool houses, if regular attention be given to ventilation, so as to economise sun-heat, but not otherwise. As I have said, however, such attempts should not be discouraged, and cultivators would do well to select only hardy varieties for this purpose. That would ensure them success as much as anything. The Black Hamburgh, which appears to be the variety mostly grown, is not the best subject for cool treatment: it is too late, and particularly liable to mildew. The Royal Muscadine, or Chasselas de Fontainebleau of the French, is one of the best, and least liable to mildew of any Grape I know. The fruit hangs a long time after ripening, too, and beats not a few early summer Grapes in that respect. Some of the most deliciously-flavoured Grapes are likewise early, and may also be planted, such as the Frontignans and Chasselas Musqué. The treatment of Vines under the cool system must be different from that usually followed in heated Vineries, where moisture may be spilled without fear. The Vines should not be encouraged to start early in the season, otherwise late frosts may happen severe enough to penetrate an unheated house and nip the buds. Much will, however, depend on making the most of sun-heat, by never admitting too much air, and shutting up the house soon after mid-day on fine bright days. Three weeks or a month, or perhaps even more than that, may be gained by attention in these matters. Moisture should never be spilled in the house, except in fine dry weather. A muggy, close atmosphere has to be feared more than anything else—it is so difficult to dispel stagnant air and moisture in an unheated house; and this difficulty is sure to be experienced during spells of cold dull weather, such as we often have during the spring and early summer months. After the fruit is ripe, the same causes are against the preservation of the fruit, and the Vinery at that season should be kept as dry and airy as possible till all the fruit is used.—*Field*.

LATE BLACK HAMBURGH GRAPES.

I SUPPOSE it is not disputed that most people, if not all, who are in the habit of using Grapes as a dessert fruit, prefer good or even second-rate Black Hamburgh and Muscat Grapes to such varieties as Lady Downe's, Black Alicante, and Gros Colmar when they can have them. There are some, indeed, who will not have any of the three just named under any circumstances, and Gros Colmar least of all, notwithstanding its fine appearance. There can be no doubt about the fact, however, that the so-called "late Grapes" fill a great gap in our supply, and that their regular culture and preservation throughout the winter and spring months constitute an advanced step in Grape culture; but it may be asked, nevertheless, if the extension of the culture of such coarse varieties has not restricted the culture of better sorts within narrower limits than is desirable. I do not refer to the now almost abandoned practice of forcing such kinds as the Black Hamburgh, Muscadine, &c., in early spring, but to the increasing practice of growing the Lady Downe's and Alicante as a late autumn and late spring, and sometimes even as an early summer supply, when better sorts ought to be on the table, and produced at little more cost than late kept ones. It is not long since Black Hamburghs and Muscats used to be supplied in good condition till Christmas at least, and often later, much more commonly than at present. Indeed, I know many large gardens in which Lady Downe's Grapes are regularly sent to table by December, and not a few where they are cut early in November, when Black Hamburghs should be plentiful and good. I do not mean to say that we are less skilful in keeping the tenderer Grapes than we used to be, but I am afraid the ease with which late Grapes can be produced and preserved has made us more careless in that respect.

It is soon enough to cut late and inferior flavoured varieties by the new year, and the supply should not be prolonged beyond the end of April, in private gardens at least, and it has often appeared to me that horticultural societies would do wisely to discourage the production of these at such seasons of the year. There is no doubt that the Black Hamburgh can be easily preserved in fine condition till January, and even till February, at which season I have seen it hanging scarcely shrivelled, and still excellent in flavour. Only a few years ago we preserved our late Hamburghs plump and good regularly till the middle of January, and would do so still were it not that owing to an increased demand they are finished considerably earlier; but I am making arrangements for going back to the practice again if practicable.

In order to have Hamburgs late it is not desirable to start the Vines too soon; indeed, they should be kept back as late as possible, or till the buds break naturally, as used to be the practice when the construction of Vineries enabled us to take the Vines outside till the time came for starting them. But even in our modernly-constructed Vineries there need be no difficulty in this respect, for by keeping the ventilators open it is easy enough to prevent growth till May, or later, and Black Hamburgs started at that season and pushed on in a moderate temperature will ripen about the beginning of October, which is about as good a season of the year for ripening Grapes generally as we have, and the fruit will keep at least three months later. As to Muscats, they need to be started earlier, of course, and it is well known that they will keep even longer than Hamburgs. Both varieties would, perhaps, need a little more attention after they were ripe than the Lady Downe's variety to prevent damping, but when fairly well ripened and kept hanging in a cool dry atmosphere they keep wonderfully well. The Royal Muscadine, though a tender and thin-skinned Grape, is also a good keeper; a bunch left on an early-ripened Vine has hung in fine condition till quite lately, and when cut was still plump and firm, and of full colour and flavour. I suppose the French "bottle" this Grape in the same manner as we do late ones. J. S. W.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Heading Down Old Plum Trees.—Many an old Plum tree that now seems hide-bound and stunted, making but little wood, small foliage, and producing scarcely any fruit, and that small and ill-formed, would, if the head were sawn off, shoot again with such vigour as to astonish most people who had never seen the plan tried. I have seen trees that were come to a complete standstill, as if they had reached their full limit of life, restored to full vigour, and given another long period of fruitfulness, simply by cutting off the branches pretty close to the main stem. Of course, the latter was healthy, or this result could not have been as I have just stated. I noticed in an orchard last summer several Damson trees that had been headed down the year previous, and that had made a vigorous start; in some instances the main shoots were a yard long, and these again were clothed with laterals the whole length, and the whole of the young growth was loaded heavily with clusters of fruit, whilst old trees that had not been pruned were without fruit or had only a few thinly scattered about on them. Wall trees may be treated in the same manner with equally beneficial results. Indeed, all kinds of stone fruits, such as Peaches, Apricots, and Cherries, may, in certain cases and under some conditions, be headed down with advantage. Many a tree that is condemned to be destroyed might have its lease of life usefully renewed by heading back, always presuming that the trunk is in a sound condition.—E. HOBDAV.

Clearing Peach Trees of Leaves.—Most fruit growers will agree with Mr. Baines on this subject. I think it is of exceedingly little importance whether the leaves are swept off the tree or not when they are ready to fall, even should they be green. I daresay most cultivators have noticed that the Peach will carry its leaves long after the wood is perfectly ripe and the buds filled up, if the house be kept warm for the season, but lower the temperature for a day or two, and let the night temperature drop below 40°, and yellow leaves and a general downfall will be the result in a wonderfully short time. This applies to Peaches under glass only; it is very seldom the leaves are allowed to hang on the trees outside till the wood is ripe; the frost cuts them off before that time.—C.

Rapid Leaf-shedding.—The rapid manner in which fruit and other trees have cast off their leaves this autumn is very remarkable. Only a short time ago the foliage was as green as it usually is in August; then came one or two severe frosts, followed by a gale of wind, and the trees are now nearly bare. The question is worth consideration as to what influence this early—considering the season—and rapid defoliation may have upon our next year's crop of fruit. One of the chief lessons taught by the late sunless, dripping summer is keeping the summer's growth thin, and the roots near the surface, thus securing good substantial foliage and early maturity.—E. HOBDAV.

Peach Growing on the Extension System.—Allow me to reply to "J. S. W.'s" queries (p. 428). In the first place he asks me to inform him where I gained my experience and knowledge on this subject—a question so irrelevant that I can only satisfy him by saying that they were gained by years of practical observation in a school evidently superior to that in which the so-called extension system is advocated, and in practice, the result of which appears to be, according to "J. S. W.," one solitary Peach to a square foot. If your correspondent can convince any of your readers that such a

crop is equivalent in value, either commercially or otherwise, to ten good 7-oz. fruit in the same space, he will lead me likewise to exclaim, "wonderful!" It is unfair for "J. S. W." at this season of the year to doubt the number of fruits which the trees here have borne; however, I trust that I shall be able to show similar crops for years to come; such crops as cannot possibly be borne and matured, year after year, by the "wear and tear," which system he so persistently advocates. As to the figures 12 in. by 12 in. equal 144 in., they do not apply in my case, as the trees bear on both sides of the trellis. Further he tells me that I am completely in error by saying that Pears, Apples, *Cratægus pyracantha*, &c., do not come under the same head, and again, "What is a cordon?" Let me reply by asking, "What have I to do with cordons?" As regards pyramids let me say that I have in this adverse season gathered bushels of excellent Pears from trees planted eleven years ago, and which are now perfect specimens, the result of annual winter prunings; and I think it ought to be clear to everyone that it is impossible to form and furnish such trees by leaving season after season the terminal bud to break first and take the lead. As with fruit, so with buds and everything else—the more numerous the offspring the less able is the parent to support alike each separate individual. Summer pinching and pruning when the sap is in full flow is injurious, inasmuch as it causes the buds to become excited, which should by nature be at rest till the coming spring. As regards Mr. Groom's remarks, I have yet to learn that Peaches have so great an objection as he asserts to good manure and stimulants. For myself I use the best cow manure I can get, mixed with fresh fibry loam—a mixture into which I find the roots to work and revel. Gorging, however, sooner or later brings on destruction.—T. COWBURN, *Sumbury Park*. [We have seen examples of the fruit produced by Mr. Cowburn's pyramid Pears, and may remark that they were in every way excellent.]

Grafting on Different Stocks.—Mr. D. Simmons states, in the *American Rural Home*, that he grafted the Pear on the Crab last spring. The scions grew well till summer, when they died. Mr. Allis had met with success in grafting Apples on Crabs and Pears on Thorns. He had also grafted Pears on common Apples and "they did well." Mr. Smith knows of an instance in the eastern part of the State (N. Y.) where the Pear does well on the Mountain Ash.

Pitmaston Duchess Pears.—We notice some very fine Pitmaston Duchess grown by Mr. Wildsmith on a west wall. This is probably going to be the greatest of our English Pears; and, considering the bad season, the fruits are very fine, and more like those that would come from districts much to the south of Paris.

PRUNING GOOSEBERRY BUSHES.

As the season most favourable for this operation is now at hand, it may not be amiss to warn the inexperienced not to cut away too much of the young wood, as the finest fruit is produced on shoots of the preceding year's growth, and it is by no means a rarity to see Gooseberry bushes stubbed in as closely as Red Currants that bear their crop on spurs set thickly on the old shoots. I have generally, when contemplating the removal of any old Gooseberry bushes, left all the preceding year's young wood intact, and the quantity of fruit which they have produced has been enormous. As the demand for green Gooseberries has of late years greatly increased both for culinary purposes and for preserving, one may, by gradually thinning the crop, get a much greater return from unpruned bushes than from those in which the wood is thinned on the supposition of the fruit being left to attain its full growth. Moreover, generally speaking, green Gooseberries are now much more esteemed for preserving than ripe ones; therefore the crop can be thinned out when half grown and turned to profitable account. In pruning, the best plan is to cut away all cross pieces and such shoots as grow low enough for the fruit to be splashed or soiled by heavy rains; then remove any old, weakly shoots and shorten back the tips of all the best placed young ones, leaving a regularly balanced umbrella-shaped head. If birds are troublesome to the buds, stretch thread across the bushes several times, or syringe them with a mixture of lime and soot. A top-dressing of well rotted manure lightly forked into the soil early in the season will greatly benefit the trees; but if not done until spring, it will be best placed on the surface, as disturbing the soil when drying spring winds are prevalent would probably do more harm than good. If one takes the trouble to examine the fruit-buds of bush fruits just after the leaf drops, it will be found that they are daily swelling up, as if about to burst into leaf; in fact, there is no such thing as an absolutely dormant season with trees either evergreen or deciduous, although we are too apt to cling to the notion that the fall of the leaf denotes a total cessation of all activity until fresh life is imparted by returning spring. There is, however, little

doubt that the roots of such trees as the Gooseberry are more active now in laying up a store for next season's crop than they are when visible growth is being made above ground.

THE INDOOR GARDEN.

PENTAPTERYGIUM RUGOSUM.

A SINGULARLY beautiful shrub, native of temperate regions in the Himalaya Mountains, where it was first detected by Dr. Griffith, and subsequently by Drs. Hooker and Thomson; but to the late Mr. Thomas Lobb the merit of introducing it is due, when he was collecting for Messrs. Veitch & Sons, about twenty years ago. In its native country it is often epiphytal, forming a large tuberos root-stock or rhizome on the trunks of lofty trees. The coloration of the flowers is quite unique in this and two or three other members of the same family from the same country. In brilliancy the colours are, perhaps, not equal to many of the self-coloured Thibaudias, &c., which inhabit the Andes of South America, but the curious blending and figuring of the colours is, perhaps, without a parallel. The five-winged calyx is a deep red, almost claret, colour, and the

Pentapterygium (Vaccinium) rugosum; natural size.

ground colour of the strongly five-angled corolla is a kind of creamy yellow or nearly white, whilst the transverse bars vary from deep red to purple, and the short lobes are tipped with green. Dried specimens of this species were, if I remember rightly, distributed by Drs. Hooker and Thomson under the name of *Vaccinium rugosum*, by which it is still known in gardens. The accompanying engraving was made from a drawing of a portion of a plant which flowered in the Temperate house at Kew this year; *P. flavum* has stouter branches, broader glossy leaves, and yellow flowers; and the only other species of the genus, *P. serpens*, is a trailing epiphyte, having crowded leaves, similar to those of *Pernettya mucronata*, though rather larger, and deep red flowers. The flowers of several species of the neighbouring genus, *Agapates*, have the beautifully variegated coloration of *Pentapterygium rugosum*, notably *A. macrantha* and *A. pulcherrima*, both of which have been in cultivation and are figured in the "Botanical Magazine" as *Thibaudias*. *A. macrantha* is a superb plant. The flowers, which sometimes exceed 2 in. in length, are yellow at the base and tips of the corolla, and the ground is white, suffused with red, and streaked with crimson. *A. pulcherrima* is remarkable for the abundance of its deeper-coloured flowers, which are borne in clusters along the long leafless portion of the branches below the leafy tips.

W. B. HEMSLEY.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Standard Pelargoniums.—There are many varieties of the large family of Pelargoniums that are peculiarly adapted for the production of handsome standards, in which form they are more ornamental than when grown as bush or trained plants. For this purpose the Ivy-leaf, Unique, and several of the variegated kinds are admirably adapted. The Ivy-leaf kinds have a habit of growth that needs some kind of natural elevation to enable their beauties to be seen to the best advantage. Naturally pendent or trailing, they do well as basket plants where this form of growth can be fully displayed; and, for this particular reason, the elevation of these upon tall stems, in the form of standards, also enables the trailing habit of the plants to be conveniently seen. How much prettier to see their elegant leaves and flowers hanging in simple profusion, with unconstrained growth, than to have the plants stiffly trained and tied as pyramids, or fan-shaped as window plants! I have seen several varieties of the old Unique formed into handsome standard heads of some 15 in. to 18 in. in diameter, blooming most profusely, and looking most beautiful amongst masses of dwarfier plants. Some of the golden and silver variegated kinds not only graft or bud easily, but form handsome ornamental heads, especially those that are not of a too formal habit. Stocks for standards are easily raised by obtaining seeds from any of the common scarlet zonal kinds, and keeping the plants in small pots until they reach from 18 in. to 20 in. in height; then, the side growths being removed, the buds may be inserted in the stems, just as Roses are budded, but with a little growth attached instead of a mere bud. The spring is the best time for budding, and during the summer good-sized heads are formed. Of the Ivy-leaf kinds, some of the new and more woody ones are best suited for this purpose, as they more readily attach themselves to the parent stocks.—A. D.

Glazing Without Putty.—One is not a little surprised to see that so many horticultural builders still adhere to the old plan of glazing with putty outside, considering that it has been demonstrated beyond a doubt that glasshouses can be made permanently and perfectly water-tight without it, thereby saving both unnecessary labour, expense, and after trouble. Those houses in which the glass is simply bedded in putty, and that as thinly as possible, can be glazed in a very short time, and afterwards there is only the wood to paint, and no after peeling off of the putty from the astragals can happen. It is only necessary to cut the panes to fit closely, and press them well down, and tack them in at the bottom, and afterwards in painting to just bring the brush about an eighth of an inch on to the glass. This, together with the usual care in bedding the glass, renders the roof perfectly secure from drip. We have had pit lights glazed here on this plan for years, and they are perfectly sound and firm, though they are moved about every day. We should, however, recommend copper instead of iron nails for tacking.—J. S. W.

Potting Eucharis amazonica.—This does best when not too frequently shifted; a large quantity of it is grown here for flowering about this season, and I find that it always produces the fewest flowers the season in which the roots have been repotted. Our plants, mostly in 10-in. pots and thereabouts, were last repotted in the spring of 1877, and they have been annually top-dressed since, but not thickly, because the pots were such a mass of roots that little soil could be removed to make room for more. The first year (77) they flowered tolerably well, last year better, and this season best of all. The pots are well filled with bulbs, and I think I may say that every bulb has produced a strong spike of flowers. The plants are hardly ever rested, certainly not subjected to the cool treatment sometimes practised. They are grown in a stove heat all the year round, plunged in a sand bed during the growing season, and watered regularly with weak liquid manure, and in August they are lifted out of the bed to keep them a little drier till they show flower. They keep producing flowers now and then throughout the whole year, but this is the time when we have flowers in profusion.—J. S. W.

Neapolitan Violets.—In reply to "W. T." (p. 450) who asks for information respecting these beautiful Violets, allow me to tell him that we have been gathering good flowers from them all through October, therefore the Neapolitan cannot be termed a late variety. I have grown it for years, and have gathered blooms from it all through the winter and spring by following a few simple rules, as this sort is quite useless if planted out and left to itself like ordinary single flowered kinds. In April, when the plants in frames are becoming exhausted owing to being long in flower, the plants are taken up, and a sufficient quantity of strong rooted side runners is taken off and planted on well enriched soil in a border that is shaded from the midday sun. They are put in about 1 ft. apart each way, and kept well watered whenever periods of drought occur; a good washing with the garden engine also greatly invigorates them after a hot day in summer. All runners are cut off with a pair of Grape scissors quite close to the crown, the object being to concentrate all

the strength of the plant for flowering instead of producing runners. Frequent surface stirrings with a light Dutch hoc keep the ground clear and the surface loose and friable. We water with weak liquid manure from the cowyard, and have never yet seen Violets injured thereby, or from the presence of thoroughly rotted cow manure in the soil. About the latter end of September we lift the clumps by thrusting a steel fork down between each plant on all four sides, taking up the ball of earth and roots intact. These are set in Cucumber or Melon frames, quite close to the glass, using the partially decayed turfy mould in which the Cucumbers, &c., have been grown, for the Violets. I feel certain that if "W. T." follows the course just recorded he will acknowledge that the Neapolitan is as early a Violet and as good as any sort grown. This spring our stock of it for propagation was both limited and weakly, but by following the system of culture just named we have now a long range of pits full of plants full of buds and flower. This Violet is essentially an amateur's flower, as it requires no heated structure in which to grow it, but simply some ordinary Cucumber frame for its winter quarters. Ventilate freely on all favourable occasions, and cover well to exclude frost as soon as the latter becomes very severe.—J. GROOM, *Linton Park.*

LEAFLETS.

WHEN in Battersea Park the other day I saw one of those ugly displays of stiff bare beds, which are unhappily common everywhere now-a-days. How badly all this kind of thing accords with the changeful and splendid beauty of the autumnal garden! As any one may have seen during the past month, where there is the least attempt at picturesque or natural gardening, or, indeed, often where there are only a few chance combinations from things being wisely left alone, the beauty of the autumnal garden is quite equal, if not superior, to that of any other season of the year.

This dismal and frightful damping and dying off of all the summer flowers, and leaving behind them great ugly graves, seriously interferes or half blots out in the best parts of gardens and country seats much of the autumn garden beauty which ought to be seen. Even those who admire it would all do well to place the beds where their uniformity and rawness would not spoil the beauty of the garden landscape.

We have heard of spring gardens, summer gardens, and winter gardens, and, not satisfied with this, some people design brickdust and painted stone gardens, but I never heard of an autumnal garden, specially designed as such, which, however, could easily be made of a most delightful type. The Grasses and perennial plants that are beautiful late in the year, the bright-leaved shrubs, the red and golden trees, and deep green Yuccas and Acanthuses—all these, and many more, would go to make a lovely and picturesque garden.

Octavia Hill pleads in the *Times* for the opening of the garden in Lincoln's Inn Fields at certain hours, for the use and recreation of the inhabitants, and especially of the children, of the crowded neighbourhood around. Lincoln's Inn Fields is the finest open space in London surrounded by brick. Immediately around it are densely crowded neighbourhoods, and to open it would be an immense boon.

The trees are very fine, and there is scarcely a chance of even spending £5000 upon it in a wasteful and ridiculous manner. It is quite a lesson in city gardening to see the trees here growing so nobly because out of the reach of mutilation. A little wise clearing away of rubbish, and planting summer-leaving trees that will flourish, is all that is required beyond simple tasteful grouping.

In reference to the notice of the Ginkgo tree (p. 430) Mr. Marnock writes: "I may say that in August, 1847, I visited the Botanic Garden, Vienna, and tracing to some memoranda made on the spot, I copy the following:—'Just within the entrance gate is a Salisburia, about 35 ft. in height, said to be the largest in Europe. The tree is divided at the base into two main branches, and is now for the first time bearing fruit. The fruit, of which there are two, are light green in colour; one about the size of a small marble, the other considerably larger. In shape both are slightly elongated.' This is no doubt the same tree which is now annually covered with numbers of yellow fruit."

The annual battle of the boilers is being fought over again in the pages of a contemporary. The chief contest now, as formerly, seems

to be between the tubular and the saddle. Strong assertions on one side are met by equally strong assertions on the other. It is, perhaps, well to bear in mind that anything that has been in existence more than a quarter of a century, and which still makes headway, cannot be altogether bad. Mr. Douglas is not far wrong when he recommends the saddle for small places, and the tubular for combined works.

The "British Medical Journal" prints some remarks about the ill-effects to be experienced in newly-painted houses. I have known illness to result from the smell of fresh paint, and that even in the case of healthy and young persons. So far as the inside of a house is concerned I would like to see all made without paint, as is sometimes done in the case of houses in which the doors and other woodwork are made of Oak as at Thoresby, the grain of which it is desired to show.

At the recent Calvert benefit performance at Manchester, a lady wore a fine white Indian shawl, fastened over the left shoulder with a gold-mounted tiger's claw, from which depended three lovely Lapageria flowers—two white and one pink—the effect was most charming.

A lady friend ornaments her very bewitching caps with carefully dried everlasting flowers of pink, white, and yellow Rhodanthus and Helichrysums. They are gathered when fully blown on a fine day, and are carefully dried in a warm room. They are of course far more delicate and pretty than any artificial flowers.

The mention of artificial flowers reminds me of an anecdote which I heard last week. A lady at a dinner party wore a breast knot of artificial Roses. In the interval before dinner, when the children were present in the drawing-room, a little girl was attracted by the flowers, and, after examining them, exclaimed "Why, your Roses don't smell sweet like papa's! They are only rag!"

A writer in a contemporary tells a curious tale of market practices, such as we hope are not common. "I had thought," he says, "nothing could be fairer than auction sales of fruit, &c., until my eyes were opened. For instance, a grower in Jersey sends 200 cases of Pears; it is made known that they will be sold at a certain hour. If they happen to be good, Mr. Auctioneer looks out for them in this way. He employs a man to bid and buy them, and as fast as he can talk and rap they are all knocked down to ditto, ditto, ditto, and so on to the end; they are then pushed off to the Borough Market, and there sold in a few hours afterwards by another auctioneer for as much as they will fetch. The sender in Jersey may be standing by and see his goods sold, for what the auctioneer cares—he can prove that they were sold for that price, and produce his books. I do not, therefore, think it requires any critic to explain that auction sales are a farce, and, I should say, worse than that. The reason why more growers do not attend and sell their own goods in the market is because of the scarcity of standing room around the market. I myself have tried it, and with great difficulty have managed to dispose of my goods. For several summers I have been sending to salesman Black Currants, and have stood in the market and realised 14s. per bushel, when my salesman's return has been 11s.—both on the same day. This very soon opened my eyes. What has long been wanted is a larger market and more room to let the producer sell his own goods.

I believe that this and other writers have, unwittingly no doubt, done great injustice to a number of very respectable and trustworthy salesmen in the market.

I hear that a meadow 8 or 9 acres in extent has been added to the area of the Royal Botanical Garden at Glasnevin. This space it is proposed shall be utilised as an arboretum, and such an one planted with a due appreciation of the wealth of tree and shrub beauty now to be commanded in all good gardens will be most interesting and enjoyable. Few men have the opportunity of planting an arboretum, and the art is far more difficult to perform well than landscape painting, since the planter has it in his power by his labour to inspire the painter's work. I hope Mr. Moore will please all lovers of tree beauty by his new labour of tree planting, since pleasure and not merely profit is to be the great result gained by his ability.

The innocent people who write to the *Times* about the iniquity of cutting down the rotten old trees in Kensington Gardens do not know that many of them are so very far gone that there is actual danger of their falling on their admirers. Nobody could suppose that such deformed and often ugly objects could be any ornament to a park that ought to be adorned with grand and healthy trees. The

public need not be afraid that fine trees will be taken away. What they ought to insist upon, if they wish to do any good in the matter, is that a fair proportion of fine young trees should be every year planted in a thoroughly good and artistic manner. Then fine old trees would come on in due time. But even these, like the wonderful old people whose deaths are regarded in the *Times* would "damp off" in the fulness of time, and the superintendent should be allowed to remove them in peace.

Some years ago many were pleased and surprised at the beauty and the novelty of the Japanese Chrysanthemum. Well, some of our florist flower manufacturers, instead of respecting and preserving the beauty of these, apply their mathematical and globose notions of beauty to the "improvement," or really the degradation of these singular flowers, and I saw a stand of them at Kensington the other day labelled Japanese, but with all the wild beauty of the original kinds "improved" out of them, and reduced to flat and ordinary-looking things; therefore, it is to be hoped that some one will preserve the true Japanese kinds for us, if he cannot improve them.

A chattering of loud but not excellent music, mixed with the shrieking of cockatoos, assailed my ears as I entered the Westminster Aquarium to see the Chrysanthemum show, while the eye was at the same moment gratified with the movements of an acrobat high above the head.

The most charming things there were those beautiful Japanese Chrysanthemums, which are, without doubt, the finest addition that has recently been made of any varieties of flowers to our gardens. One white kind was a beautiful bouquet in itself, and the delightful and fantastic shapes, the fine, and often singular, colours of the others were such as would charm those who are often disheartened by the formality of a Chrysanthemum show.

Mr. J. Douglas is of the same opinion as myself as regards the need of preserving these beautiful Chrysanthemums pure and in their original beauty, and as he has some influence with growers, perhaps we shall succeed in putting an end to the misguided attempts to improve them. If I were a rich man I would offer prizes for the encouragement of these flowers in all their distinctness of race.

Turning from these to the Pompones, tied down in the stiffest way and trained in globular heads, the change was a depressing one. Surely we want a "break" in our Chrysanthemum shows. Those miserable contortions of plants tied down with string into shapes compared to which a mop is picturesque, is not the last and highest expression of good culture in Chrysanthemum growing! If only for variety's sake, it may be worth while to have plants grown in a free and natural manner, and not tied down at all; and a plant grown so that it does not lose its leaves is a beautiful one.

Mr. Peter Veitch tells me that in China, as one might expect, a wholly different mode of cultivation is pursued. I once noticed a line of plants grown in a Celery trench; they preserved their leaves well, and, carefully transferred to pots and moved into the greenhouse at flowering time, they looked well both in flower and in foliage.

This mixing up of music hall, menagerie, public-house bar, and ceaseless jingle form a combination of sights and sounds in which it is exceedingly difficult to properly study the quiet beauty of flowers. It suggests how badly we are off in London for some central horticultural hall, in which interesting exhibitions of this kind could be held under conditions more agreeable to all concerned.

There are many little Chrysanthemum shows about town which many of us never see, and it is much to be desired that we really had a large representative Chrysanthemum show in the metropolis every year. With the fine varieties of flowers that there is now, if growers could be got to break away from the umbrella type and treat the plant from the point of view of those who wish their conservatories decorated, and also from that of the higher one of preserving the natural form and vigour of the plant, we should have a very beautiful exhibition.

A new and beautiful flowering tree is such a great novelty that one has peculiar pleasure in reading the following in the *Rural New Yorker*:—"Mr. Douglas writes us that he has travelled several thousand miles to convince himself of the value of *Catalpa speciosa*, and he believes it to be of incalculable value to this country as a forest tree, and a much finer ornamental tree than *C. bignonioides* or *syringefolia*, as it is much hardier—a more upright grower, and produces much more beautiful flowers."

The sooner our American friends send us this the better. One of the few trees that do thoroughly well in London is the common *Catalpa*. Even in crowded parts of the city handsome trees may be seen flowering profusely, and they retain their foliage a long time very late in the autumn, notwithstanding the dense smoke and dust of the streets.

I regretted to see a large stand of ornamental Grasses recently very stiffly and closely arranged, and quite spoiled by the admission of certain kinds dyed with crude colours, so as to make the whole look very artificial. What a beautiful exhibition these would make if properly arranged and classified; they would come very well in the Chrysanthemum season, and ought to be shown much better than is now the case, and Messrs. Hooper, who have a large collection, could surely show us something beautiful in this way.

In reference to this newly-awakened interest in winter bedding, which the Messrs. Lee's beautiful display at South Kensington recently has served to arouse, I may mention that I hear the winter bedding at Heckfield Place is this year much more attractive than usual. No doubt, the moist summer, inducing good growth on the part of the many dwarf shrubs and plants employed, has assisted to bring about this result, but something is also due to smaller materials being used in the production of mass effects. Still, the great feature of the winter display there is the fact that it is but a part of the summer arrangement; therefore, it is only necessary in the autumn to remove the more tender plants and fill up with hardy ornamental shrubs to at once make the design complete. In this way the additional cost is trifling.

The bright Geraniums, if one may still venture to use the older name, which are now adorning with such bright and lovely colours, such houses as Mr. Cannell's, at Swanley; the Cyclamens, of which Messrs. Sutton showed a very large batch a year old from seed the other day; the many double Primroses which came from Burghley to Kensington last Tuesday; Vilmorin's single variety, of which a batch came from Chiswick, and some new and cheerful-looking Salvias, shown by Mr. Cannell, are only a few of the gay flowers that help to mitigate the dullness of the winter for us. With such attractions, and no doubt many more to come, a well-built and well arranged greenhouse will, in the future, be more indispensable than ever.

Sir Joseph Hooker, in a recent number of the "Botanical Magazine," says: "It is indeed astonishing that the Asters, Helianthus, Rudbeckias, Silphiums, and numberless other fine North American herbaceous plants, all so easily grown, and so handsome, should be neglected in English gardens, and this in favour of carpets, hearth-rugs, and ribbons—forming patterns of violent colours which, though admired from being the fashion on the lawn and borders of our gardens and grounds, would not be tolerated on the floor of a drawing-room or boudoir." This is the just appreciation of the value of hardy plants which one might expect from a traveller who has seen so many of the most beautiful and distinct of hardy plants "at home" in all the quarters of the world.

I hear with regret that the botanical collections of the India museum are about to be transferred to the museum at Kew, so if the report be true the hope that has been generally entertained that all the national natural history collections would be centralised in the new and commodious building at South Kensington must now be abandoned. That Kew Garden is by no means an appropriate place for such museums is patent to every one who is in the habit of visiting them, especially during the present short days, *i. e.*, the three hours a day during which the public are admitted.

Lately I have been a frequent visitor to the museums at Kew, and in the majority of instances I have been the only person in the building with the exception of the attendants, thus showing what a paucity of visitors there is to these places, a circumstance which cannot be wondered at, for but few people would care to go such a distance from London for the short time during which the gardens and museums are open. This would not be the case if the museums were centralised in such a readily accessible locality as South Kensington.

What is there to prevent these museums being open by gas-light, the same as the South Kensington museum, and open early in the morning, and also be placed under the same regulations as that museum? It must be admitted that museums are in no way an indispensable adjunct to a garden of living plants, and it is to be regretted that these valuable collections which have been accumulated at Kew, and representing as they do such a vast outlay of public

money, should be placed in such obscurity, or otherwise enjoyed but by a privileged few.

*

The tank for the hardy aquatics at Kew has been raised to about 2 ft. above ground level. The walls would be better veiled with some low evergreen climbers to soften them a little. It is probable, however, that all that is necessary for science or effect could be obtained without raising the tank. Doing that of course adds to the ugly surfaces that one desires to see anywhere but in a garden. The best preparation for hardy aquatics which I have ever seen is in the Munich Garden, where the tanks are narrow, one plant occupying a few feet of each—having, in fact, a compartment to itself. I never saw hardy aquatic plants so well grown.

*

I notice that the walls of the plant houses at Kew are painted a shiny blood-red. No doubt in these æsthetic days artistic reasons could be given for any aberration of this sort, but I fancy a white stone colour, or an ordinary red brick, of which some of these house walls are made, will be found the best in the end.

*

I observe that Sir Joseph Hooker has taken occasion in the "Botanical Magazine" to deprecate the prevailing taste for carpet bedding. After this expression of opinion from the Kew Director we may in the future look for something better in the flower-beds at Kew than copies of the carpet bedding in the metropolitan parks and private gardens. Gardeners from all parts of the kingdom flock to Kew at some time or other to get lessons in horticulture, and it would be very good of the authorities there to point out by examples what constitutes good taste in floral bedding.

*

Some of the beds that border the broad walk might well be employed to exhibit the best effects in grouping shrubs, and alternate ones might be filled with good selections in families, or suitable groups, of hardy border plants. With such an arrangement there would be always something to see at Kew that would, perchance, not be done better elsewhere.

JUSTICIA.

Orchis hircina on the Ormes Head.—As the writer who first called attention to the statement that *Orchis hircina* was found on the Great Orme, I have read with much interest the numerous letters which have since appeared in THE GARDEN on the subject. I may say that when in Llandudno last month I saw and had a long conversation with Mr. Simpson, who says there is no doubt whatever about the matter, and he seemed to me to be well acquainted with *Orchids*, as, coming from my own county (Kent), the seat of British *Orchids*, he ought to be. However, I purchased plants which had bloomed during the past year, and which were no doubt taken from the Great Orme, so if I can flower them the question can be settled. As to Mr. Simpson raising a large stock from seed, I expect he will be very much disappointed, and certainly to have them ready for distribution next year, as the seed pods were taken from the plants I bought, and I gave him a hint as to sowing them, but it will take at least three years to make them blooming plants, even if he can raise them at all.—A. E.

Paris Daisies.—Under the name of *Chrysanthemum frutescens* var. *luteum* or *Etiolè d'Or*, Mr. Howard, of Southgate, is cultivating a large stock of a free blooming *Marguerite*, which differs from the common white Paris Daisy in having broader lobed, bright green, not glaucous leaves, and clear primrose-coloured flowers from 2 in. to 3 in. in diameter. We ourselves regard the plants, of which there are two forms, as a distinct species rather than as a variety of the common and less beautiful *C. frutescens*. As a winter blooming plant for decorative purposes or for the supply of choice cut flowers, Mr. Howard's Primrose, or Golden Star Daisy, is likely to prove one of the most useful of modern introductions.

Double White and Purple Rockets.—Having noticed the remarks of several correspondents (pp. 404, 367, and 295) in reference to the scarcity of these, I was somewhat surprised, for, though the double white is not nearly, I believe, so plentiful as it was or should be—the same can be said of many other old favourites—it is very far from being lost; the double coloured varieties are perhaps even scarcer because less known. Mr. Williams' admiration will not be lessened when he blooms the newer kinds, as I have done; old plants are soon damaged in constitution by careless plucking of the flowers (tearing the stems) or by disturbing the roots, and, though with care plants may be kept healthy for years on well-drained borders, as I have often seen, it is far better to keep up the stock required by means of cuttings put in yearly, placing them in cold frames until spring, or, where such quarters cannot be provided, they may be planted out in the autumn, with a better chance of standing the winter than older plants would have, care and attention in both cases being equal.—J. Wood, *Kirkstall*.

THE GARDEN FLORA.

PLATE CCVII.—A GROUP OF POTENTILLAS.

Drawn by CONSTANCE PIERREPONT.

The hybrid varieties of *Potentillas* constitute a class of showy and desirable hardy perennials, which apparently are but little known or cultivated, though the attractiveness of the excellent representations of a few of the varieties shown on the accompanying plate is in itself sufficient to commend them to the notice of every lover of hardy flowers. Like the *Pyrethrums* figured a short time ago in THE GARDEN, these hybrid *Potentillas* seem to have sprung up within the past few years, and, like them also, the double-flowered kinds are the most showy, and they possess the additional advantage of lasting a longer time in perfection than the single sorts, on the plant and also in a cut state. Though the genus *Potentilla* comprises such a vast number of species, there appears to be but few that have a tendency to produce double flowers, for, with the exception of our native *Creeping Cinquefoil* (*P. reptans*), of which there is a variety with pretty yellow double flowers, there are but two or three kinds indigenous to the Himalayas, from which have originated the present race of garden forms. These are *P. atro-sanguinea*, of which the deep crimson single flower at the top of the plate may be taken as a representative, and *P. insignis*, a species with large pure yellow flowers, shown at the extreme left hand corner. Both of these species are characterised by handsome broad deep-green leaves, the under-surfaces of which have a silvery appearance, which produces a fine contrast to the deep green upper surface and the showy flowers. All the varieties with large double flowers may be traced to these species, and it is interesting to observe the manner of the arrangement of the colours in the flowers. Some partake wholly of the colour peculiar to the original, as may be seen in the large crimson flower in the centre of the plate, and also in the pure yellow one immediately above it. In others the colours of both kinds are apparently blended and disposed in a variety of markings. Some are streaked and flaked with either yellow or crimson, similar to a *Carnation* or *Picotée* flower, and others have the petals more or less broadly margined only, while others are beautifully spotted and marbled. There seems to be about three dozen distinct named varieties, and a great number of them have emanated from Continental sources, though they may be all obtained in any of the large hardy plant nurseries. These represent every type of shade, size, and colour that it is possible to obtain, though such a large number is not indispensable, as a good selection of the most distinct kinds would be found to embrace most of the qualities of the whole race.

The culture of these plants is, as is the case with most hardy flowers, a simple matter. In my garden they luxuriate in a light deep soil, which is not very rich, though they well repay somewhat liberal treatment in this respect. The more fully exposed the position which they occupy is, the better it appears to suit them, and thus treated they soon form vigorous specimens, and produce flowers in great profusion for many weeks in succession—in fact, from the beginning of summer till the middle of autumn. By way of affording variety a few flowers of some of the original species have been introduced in the plate, which, though they are very beautiful, soon drop their petals, whereas, in the double-flowered they continue in perfection for a considerable time. The fine cerise-tinted single bloom at the extreme right hand corner at the top of the plate is a very desirable kind, as it is not only unique in point of colour amongst all the species and varieties, but it continues to flower till the end of autumn in profusion. These by no means exhaust the beauty to be found amongst the *Potentillas*, for there are a great number that are strikingly attractive, especially the Alpine class, such as the pretty little *P. ambigua* of the Himalayas, and there are many others in cultivation of equal beauty that are natives of Europe.

JOSEPH STEVENS.

Bisect.

[We are indebted to Mr. Stevens for the specimens from which our plate was prepared.]

Kniphofia carnosia.—This is a very unique plant, different in shape and habit from the other species. It is a native of Abyssinia, and was sent to Europe by Schimper. It forms several low, spreading leaf rosettes, from the midst of which rise several flower-stalks to the height of 1 ft., producing a completely cylindrical flower-spike about 3 in. long, and 1½ in. broad; but the comparative smallness of the flowers is compensated for by their glowing apricot colour, which is made still brighter by the bright yellow anthers, laden with pollen, protruding. The individual flowers open first on the top side, and, taking it all in all, it is a lovely and striking plant. It began flowering in September, and is still in bloom.—MAX LEITCHLIN, *Baden-Baden*.

Paeonia officinalis

GARDENING FOR THE WEEK.

Conservatory.

Chrysanthemums in most places are more than usually late this year, and the later kinds will in many cases only now be coming into bloom. Everything should be done to keep the foliage fresh and healthy; air ought to be given when the weather is at all favourable, for if there is any mildew, anything approaching a stagnant atmosphere will cause it to spread. Where Roman Hyacinths are grown in considerable quantities, these will be very useful in assisting to keep up the display of flowers in positions that are unsuitable for large plants, and successional stock of them will be found much more satisfactory for bringing on into bloom than any attempt to force the larger kinds until later in the season.

Greenhouse.

Brugmansias.—These plants are only suitable for roomy houses, and for such there are few more commanding objects when in flower. A mistake which often occurs is letting them get too large both in the head and at the root, for which there is no necessity whatever. They look best as standards on straight clean stems from 4 ft. to 5 ft. high. In order to keep them within bounds as to size, nothing more is necessary than to cut the heads close in after blooming, and instead of increasing the root-room, as is frequently done by means of very large pots or tubs, remove a considerable portion of the soil once a year, and replace it with fresh material. If the plants are cut in now they will occupy very little room through the winter, as they can then be set in any house or pit out of the reach of frost, just keeping the soil in a slightly moist condition.

Myrtles.—Time was when large bushes of Myrtles might be seen in almost every greenhouse, for although they will live out-of-doors in some parts of the kingdom, their leaves are not so bright looking as when they are grown under glass, particularly in the winter season, when they are of most use. Not only are their flowers pretty, and the plants, when well managed, always fresh and green in appearance, but for mixing with arrangements of cut flowers they are most serviceable; a moderate number of their green sprays may with advantage be used even in the choicest bouquets, as, besides the perfume of their leaves being agreeable, employed round the outside there is no better material for giving support to the whole. Cuttings made from the young shoots now and inserted thickly in pots filled with a mixture of sand and peat, with a little sand on the surface, well moistened, and covered with propagating glasses, and kept in a greenhouse temperature during the winter, will by that time be callused over, and if then put in a little heat will root freely. If through the spring they are kept where a little warmth can be given them they will get a start such as will enable them to make good, small, bushy plants before the autumn. Old specimens that have become at all naked and bare, may be freely cut back any time, and if affected with scale or other insects they should be frequently dipped in or syringed with insecticide before they break. If placed in a greenhouse and kept somewhat warmer than ordinary, they will start into growth in good time, and though it may not be the practice with many to reduce the heads of anything of this character until nearer the time when they would naturally begin to grow, yet I have found by thus treating them in the winter, where means exist of keeping them slightly warmer than they would otherwise need to be, that they not only get a start that enables them to make much more growth through the summer, but that the weakening influence of bleeding, that generally results when they are cut back a little time before the spring growth commences, is avoided. It also affords an opportunity for a thorough cleansing of the plants when they are at all affected with insects.

Cinerarias and Herbaceous Calceolarias.—Cinerarias intended for the latest spring-flowering, if not already placed in their blooming pots, should be so before the roots get too much matted, as, when once they get into that condition, there is less chance of the additional root-room which they receive when put in their flowering pots having its full effect in inducing strength and vigour. They will bear the soil being made very rich by the addition to good ordinary turfy loam of some well rotted manure and leaf-mould, and they should be potted firmly; I should also in all cases recommend with soft-textured plants of this description that are intended to bloom when the spring is somewhat advanced and the weather is usually dry and sunny, necessitating the application of a good deal of water, that the pots be not filled too full of soil, leaving a little more space than usual for watering. Herbaceous Calceolarias should on no account be allowed to remain in the little pots which they have so far occupied until their roots get at all matted; they will bear larger shifts than most plants; for the ordinary purposes of decoration they will, in the majority of cases, be found most useful flowered

in from 6-in. to 8-in. pots; but any one wishing to have them as strong and vigorous as possible may, by keeping them shifted on as often as is permissible, grow them so as to attain a large size, and be proportionately better flowered than smaller plants. Like the Cinerarias they enjoy the soil being made very rich with rotten manure and leaf-mould. In order to grow the above plants with anything like success they must be kept perfectly clear from green fly, for if ever allowed to get much infected with that they are certain to injure the leaves in a way that so far weakens the plants as to prevent the possibility of their flowering well, and the foliage having such an objection to severe fumigations or strong applications of Tobacco water, as soon as any of the stock becomes the least affected means should at once be taken for the destruction of the insects, examining the plants at short intervals with a view to detect them directly they make their appearance. The first batch of Cinerarias that either are now or will shortly be pushing up their bloom-stems, as also those that are later, and whose roots have got fairly hold of the soil, should be regularly supplied with manure water. The best examples of these I have ever had were wholly watered with liquid stimulants from the time they got established after the last potting, not a drop of clean water being used. There is one thing in plant cultivation always apparent when the subjects are vigorous and strong, resulting from a continued course of attentive management from their first propagation upwards, they are generally much more seriously injured by any neglect than others whose growth is of a more stunted, less free description. This is particularly the case with plants whose leaves and stems are soft in texture like those of Cinerarias, which, where really well grown, and furnished with large, stout, healthy foliage, if only once allowed to get too dry at the roots are thereby so far affected as not only to lose much in appearance, but have their flowering capabilities proportionately diminished. I make these remarks with a view to impress upon those not experienced in their culture the greater need for carefully attending to the wants of strong early propagated plants that either at the present time, or shortly will be, throwing up their flower-stems, as it often happens at this season of the year, when plants need water so much seldomer, that they quite as frequently suffer from its non-application as in dry summer weather, when the whole require it possibly every day. Especially does this occur when such things, for want of room, have to be placed on shelves over the paths, and other positions not very easy of access. The same remarks apply to herbaceous Calceolarias, though these, except those propagated from cuttings, will in few cases yet have attained sufficient size to be so much liable to injury through the soil getting dry.

Shrubby Calceolarias.—Not only are these very effective when in flower, but they are much more easily managed than the herbaceous kinds. Their woody nature and the proportionately tougher character of their leaves make them less susceptible to attacks of insects, and when affected they are better able to bear fumigation, or whatever means are taken for the destruction of the animal parasites. The plants will last for years, and with fair treatment will keep getting larger, with sufficient root-room, forming bushes of considerable size, very suitable for conservatory decoration. For use in this way they are better adapted than the herbaceous kinds or many other soft-wooded subjects, as they will bear when in bloom placing in positions where there is less light, such as would make the softer growing kinds unsightly in a very short time. Plants that were cut back after flowering, part of the soil removed, and repotted, something in the way that large-flowered Pelargoniums are treated, but with less destruction of their roots, should now be moved to the pots wherein they are intended to bloom. The yellow flowered kinds, particularly the old sort, *aurea floribunda*, are especially adapted for using in this way, as if kept a little warm through the winter, say from 40° to 46° in the night, they will flower early, and with sufficient root-room and regular liquid feeding will keep producing flowers in succession for a great portion of the summer.

Lilies.—Those that flowered the latest should now receive whatever attention they require in repotting or renewal of the surface soil; where there are not more bulbs in the pots than will have sufficient room for another season, the latter will suffice. But with all it is well at the same time to see that the drainage is efficient, for, standing about as these plants usually are a good portion of the summer on the ground or other moist surfaces, worms are very apt to get into the pots, in which case the drainage is almost certain to get more or less clogged up. From this time until spring, when the young shoots have appeared above the surface, the soil should be kept in not more than a slightly moist condition, that is, just so as to permit of the root growth that with most kinds will after this time very shortly commence. There are few finer subjects for a large conservatory than *L. giganteum*, although the plant in favourable situations will live and thrive with a little protection through the winter; yet even on the coast, in the most southern parts of the king-

dom, I have never seen it near so fine as under pot culture. Plants of this species now in cold frames or pits should have plenty of air on all favourable occasions, and, if they are expected to bloom next year, should not be allowed to suffer for want of root room, though where there is not danger of their being thus affected, I should not advise their being placed in the flowering pots until later on.—T. BAINES.

Flower Garden.

Auriculas.—Many *Auricula* growers have been fidgety about the mild weather which we have had, causing their plants to make growth when they should have been going to rest. Even small plants have been so forward as to throw up their trusses when they should have been forming strong plants to bloom in the spring. Small growers who have but one or two plants of a George Lightbody, John Waterston, or other choice sorts, see with dismay half of them showing trusses with short stems 1 in. long. To such it has been a relief to see the sharp frosts of last week and the present, a thermometer at Loxford having registered a minimum of 12° of frost. I do not think of placing any covering over the glass, frost cannot injure them at this season if the plants are kept dry. They will not want any further attention at present except to see that the lights are placed over the frames at night, and removed entirely during the day.

Carnations and Picotees.—The early setting in of severe frost is still further against the formation of roots in the case of newly potted plants. I have at last reluctantly found it necessary to put up a hotbed, using just sufficient manure to produce a gentle heat. I place some Cocoa-nut fibre refuse over the manure, and over that set the pots, plunging them just about one-third of their depth. There will be sufficient heat if it feels warm to the hand; violent heat and steam would be most disastrous in their results. The plants that are well rooted will be quite safe in cold frames; and, while frost lasts, they will require just the same attention as *Auriculas*. When thaw comes look carefully over all choice sorts, remove any dead leaves, and just stirring the surface soil in the pots if it is caked. Those who have planted out their beds will now see the value of a surface dressing of dry rotten manure. After the frost is over examine all the plants carefully, and gently press them into the ground with the fingers of both hands.

Dahlias.—I have thought that it was well to leave *Dahlias* in the ground until the frost was sufficiently severe to kill all the leaves and small stems, we therefore dug up the roots last Saturday after they had been exposed to 12° of frost on the previous night. Some of the largest growers dug up their roots after the frosts which occurred about three weeks previously. If the ground had been wet I also would have done so, but the border in which the plants were growing had actually become dust dry, and under such conditions the tubers must have been maturing. We had the convenience of a Vinery where the atmosphere was very dry, and on the floor of this structure the tubers were laid out to dry, placing them first with the stems downward, and then reversing them so that they would become quite dry all round. Afterwards they were stored away with the tubers just covered with Cocoa-nut fibre refuse; any shed or place from which frost is excluded answers well to store them in.

Gladioli.—Some have recommended leaving the bulbs of these in the ground during winter. I have never done this, and I have always found that when they were kept too long in the ground, *i.e.*, after the end of October, the bulbs did not come out clean and healthy. Those who have not yet stored their bulbs should lose no time in doing so; cut the stem over close to the top of the corm or bulbs. They must be dried in the same way as *Dahlia* tubers before storing them; each sort may be put separately in a bag, and the whole can be stored away in a box until February, when it will be necessary to overhaul them to see if any are injured by decay, and those that are starting into growth must either be potted or planted in a warm sheltered border in order to obtain an early bloom.

Phloxes, and other herbaceous plants in pots, will be quite safe in cold frames while the weather is severe; if previous instructions have been followed the soil in the pots will not be very moist, and no water should be applied while the frosts lasts.

Tulips.—The ground was in such a thoroughly dry state, and the loam that we use to cover the bulbs also so dry and in good condition, that we planted the bulbs out last week. Our bed of show Tulips is nearly 60 ft. long, and when in flower it is a very beautiful sight. One does not wonder that it comes to be the rule for the old fanciers to plant out on the 9th of November. The root-stock swells about that week, and very soon the small rootlets will appear, whether the bulbs are planted or not; and when planted the roots strike out at once into fresh maiden loam. I am rather glad that we did get them out before the frosts set in.

Hardy Cypripediums.—Some remarks were made about the repotting of these a fortnight ago. It was recommended that they

should be potted in a staple of loam and peat, and for the largest proportion of them, especially the free-growing sorts, this answers well; *C. guttatum* may be taken as an example of a slender-growing sort that would prefer turfy peat with a third part of leaf-mould. Get all of them potted at the earliest opportunity, and do not use large pots.—J. DOUGLAS.

Kitchen Garden.

The long evenings will now afford abundant leisure for devising plans for future cropping, and also for summing up the results of the past season's operations, such as noting the varieties of vegetables that have been most satisfactory, or, indeed, anything by which we are likely to profit in future. By thus mentally arranging our work in something like methodical style, we save ourselves a large amount of physical labour and embarrassment, to which haphazard cultivators must of necessity be subjected. If the hints given in former notes have been acted on, all root crops will now be securely stored, and when bad weather impedes labour in the open air such root stores can be overhauled. Potatoes will need frequent examination, for probably they will keep but indifferently through having been harvested under such unfavourable conditions. Onions are already growing out fast; they were housed so full of moisture that the only conditions under which they are likely to keep will be a cool, dry, and dark room, and all disposition to grow must be repressed by a bend at the neck. Examine Cauliflowers and Early Broccoli daily, for the purpose of either cutting or sheltering from frost all that are ready for use. Cauliflower plants under hand-lights will now be the better for having the lights put over them at night, for though they may not seem hurt for some time, a few degrees of frost cripples or stunts them, and this leads to "buttoning." Those plants that were pricked out at the foot of south walls will now require shelter in order to ensure their safety, and the same remark is applicable to Lettuces and Endive. Plants of these that are fully grown are best lifted with balls of earth and planted in orchard-houses, cold pits, or frames. Besides affording protection and arranging details as regards forcing Asparagus, Seakale, and Rhubarb, there is little else of a routine character that now demands attention, and therefore the present will be a good time to undertake extra work, such as making new walks, opening or putting in new drains, planting Box edgings, levelling, grubbing, trenching, and, indeed, any work for which time cannot be afforded during the busy season.—W. W.

Indoor Fruit.

Pines.—With the exception of fruiting plants in an advanced stage, all others should, for the next few weeks, be kept in a partial state of rest; none should now have a greater bottom-heat than 70° to 75°, and the maximum top-heat need not exceed 60°, unless the weather proves to be exceptionally mild, under which circumstances a proportionate rise may be allowed. Plants that are swelling off fruit must still have the most generous treatment, and, therefore, to do them full justice, a separate compartment is indispensable; these still require the maintenance of a bottom-heat at 80° and an atmospheric temperature at 70°, and, though water will not now be so often required as hitherto, they should never be allowed to get really dry, for, if ever they thus suffer, the result is either deformed fruit or else badly-swelled pips. Smooth Cayennes, being shy producers of suckers, the crowns of all fruit of this variety as used should be preserved, as they make equally good plants as the finest suckers, the only difference being that they are longer on hand. The old fruiting stools, with any suckers which they may have on them, should be permitted to retain their fruiting positions till the general overhaul, which will be required about the beginning of the new year, takes place.

Vines.—The present month is generally a most anxious one for those having a quantity of Grapes still hanging on the Vines, for, unless they have been well ripened, the probability is that cracking and damping off will be prevalent, and, though it may be impossible to entirely stop such occurrences, much may be done to check them by daily removing all bad berries, and by keeping the atmosphere dry and warm, and removing all surplus shoots that have hitherto been left as root producers. Good keeping can only be secured by thorough and early ripeness, and any who are troubled because their Grapes are keeping badly would do well to in future start their Vines earlier. Some are prevented from doing this under a belief that if ripe too early the Grapes would shrivel before they were required for use, but with late Grapes this is never the case; but in early houses with Grapes ripe in May or June it would be marvellous if they did not shrivel, considering both the varieties of Grapes that are grown for early use, and the weather at that season. Prune Vines in mid-season houses as soon as the Grapes are cut, and, where there are but few remaining, cut and bottle them, in order that the Vines may receive the treatment most conducive to rest, *viz.*, plenty of ventilation.

Peaches and Nectarines.—The earliest house may now be kept closed up, but fire-heat should not be applied for a week or two, unless the temperature approaches the freezing point; and, till artificial warmth is afforded, the trees will not need to be syringed, but as soon as heat is turned on, then syringe the trees twice a day. The Peach will not bear hard forcing, therefore proceed slowly; great fluctuations in temperature are ever to be avoided in all fruit forcing, but especially with Peaches, which are liable to drop their buds before opening. If the borders are inside, see that they are thoroughly moistened through, and always use tepid water. All that outside borders will require will be sufficient covering to keep out frost. The trees in late houses may for the present continue fully exposed, but the lights should be put on when there are indications of a long-continued frost. New houses that are to be planted should have the borders prepared at once, in order that the trees may be got in this month. Inside borders are preferable, because they can be treated exactly as desired, and at any time as regards feeding and watering.—W. W.

Extracts from my Diary.—November 24 to 29.

FLOWERS.—Potting Fuchsias for winter blooming. Looking over bedding plants and picking off decayed leaves and blooms. Rearranging plant houses. Taking a few more Hyacinths from outside and putting them in heat. Potting crowns of Lily of the Valley for forcing. Fumigating house in which Azaleas and Carnations are for destruction of green fly. Getting a few more Spiraeas in heat. Planting two Camellias on back wall of early Peach-house. Fumigating Cinerarias in order to kill green fly. Sponging Stephanotis on roof of stove. Plunging *Eucharis amazonica* in bottom-heat.

FRUIT.—Looking over Muscat Grapes, and cutting out decaying berries. Watering all Pines requiring it. Watering early forced Peach-house previous to top-dressing with some 2 in. of fresh loam. Planting standard Cherries and staking them securely; also painting their bases with tar to keep off vermin. Making up bed in deep pit for plunging first batch of Strawberries, to induce them to make root before starting. Digging round and root-pruning Cherry trees to retard rank growth. Mixing lime rubbish with chopped loam for adding to soil when planting Cherries. Nailing Peach trees in early house. Uprooting exhausted Melons in house. Emptying Peach-house of old trees and soil preparatory to planting afresh with young trees. Renewing linings to Pine pit. Looking over Apples and Pears in fruit-room.

VEGETABLES.—Digging ground for spring cropping. Sowing Golden Trophy, Little Gem, and Acme Tomato seeds from America. Turning manure for Mushroom beds, and covering up first spawned bed outside with mats and straw to exclude rain and frost. Preparing stage for French Beans in Melon-house. Potting Golden Gem, Trophy, and Acme Tomatoes out of seedling pots into 3-in. ones for planting in Pine stove for early spring use. Cutting all Autumn Giant Cauliflower ready for use. Looking over Lapstone Potatoes in heaps outside.—R. G., *Burghley*.

Iris foetidissima variegata.—I am glad that "An Old Gardener" has (p. 444) had the courage to bring this plant so prominently before the public. No plant is more beautiful or persistent in its variegation, which is far handsomer than that of many stove and greenhouse plants; indeed, it in every way equals that of the well known *Aspidistra lurida variegata*. I saw it lately offered for sale by some French florists in Liverpool, tied up with great care, and exhibited in the plate-glass window as if it were some Brazilian Orchid. The plant is perfectly hardy, and easily propagated; anyone having a dozen may soon have a hundred. Properly prepared it would be very striking as a winter bedding plant, after the ordinary summer bedding materials have been cleared away. A few beds of this, edged with some of the Mossy Saxifrages, would be very attractive from October till May, and even then few people, I think, would venture to disturb it. It is also useful for massing among shrubs in bare places, where little else would grow, bushy and shady places being its habitat in the south; I mean the type. It is very common in Devonshire, and is known as the Roast Beef plant, from a peculiar smell which the bruised leaves have.—THOS. WILLIAMS.

Hardiness of the Procumbent Fuchsia (*F. procumbens*).—The hardiness of this pretty trailing New Zealand Fuchsia has been well tested by Mr. Green at Pendell Court, Bletchingly. He has several plants of it which have withstood with impunity several winters unprotected, including the last severe one. The chief point is affording it a thoroughly drained position, and then it appears to be perfectly safe. The plants at Pendell Court are growing on a raised mound, and, therefore, are comparatively dry in winter.—W. G.

THE KITCHEN GARDEN.

ONIONS AND ONION CULTURE.

I FIND the Trebons Onion—a large globe-shaped variety that may be considered intermediate between the Tripoli and the White Globe—to be an excellent variety for culinary purposes. The Trebons is a soft and tender Onion, and therefore not a good keeper; but, like the Tripoli, it is not so strongly flavoured as some other varieties. It is on the whole an Onion of quick growth, that is to say, it turns in pretty early, and therefore does well for use after the autumn-sown Tripoli, and before the main crop keeping Onions are required. I think it was originally introduced by Messrs. Vilmorin, of Paris, and when a few years since a large trial of Onions was made at Chiswick, a first-class certificate was awarded to it.

I think that, as a rule, cultivators do not sow their Onions so early as they should do. The Oxfordshire growers, who give the Onion as much attention as some florists give their Auriculas, sow their seed in the end of January or early in February, as soon as the weather is favourable, and thus they ensure a good start. Onion seeds should be sown in dry weather, when the soil can be crumbled almost to powder, and rolled down firmly. Though the Onion is generally regarded as a shallow-rooting plant, it strikes its roots much deeper into the soil than some persons imagine, and those who grow it well dig the soil deeply. Some are found recommending a depth of 2 ft. and 3 ft., manuring heavily at the same time. It is best to trench the ground early in December, and, mixing in the manure at the same time, throw it up roughly to take the frost till sowing time. A good loam, not clayey and cold, but fairly stiff, is best adapted for the Onion, and the situation of the bed cannot well be too open. If the soil is light and somewhat sandy, some stiff clayey loam should be mingled with it, or it is likely to fail at a critical time when the Onions should be making their prime growth.

We do not, as a rule, transplant Onions in this country, except when the crop is likely to be a thin one. The Oxfordshire growers who grow for exhibition do not depend on transplanted bulbs; they sow thinly good seed, and thin out the plants in the rows to a good distance apart where necessary. It is said that in Portugal, where so many of the Onions are grown that are imported to this country, the cultivators sow thickly in beds in the month of November, and transplant in spring into very rich soil, and in this manner produce many of their finest bulbs.

The best sorts of Onions for a garden are the White Lisbon, sown in July for young Onions in spring; and the white and red Italian Tripoli, sown in August. The Tripoli can be sown in store beds, and then transplanted; or in drills and thinned out, as in the case of the spring-sown varieties. For spring sowing, use White Spanish, now having many *aliases*, the White Globe, and James' Keeping; sowing the Tripoli early for late summer use, but they succeed best on a warm, light, sandy soil. The late Mr. John Standish used to grow wonderful Tripoli Onions during the summer in his nursery at Ascot.

The great bulk of the White Spanish Onion seed is grown in Bedfordshire, and of James' Keeping Onion and White Globe large quantities also. The seeds of Tripoli Onions, the Trebons, Strasburg, Brown Spanish, Blood Red, and Silverskin, come from the Continent and America. If the quantity of White Spanish Onion, estimated by hundredweights, that one of our leading seed houses gets through in a season were set down, it would be regarded by many as incredible. It is only those who know something of their business transactions that can understand the immense bulks required for a season's trade.

R. D.

Eclipse Cauliflower.—Mr. Miller (p. 391) speaks of Veitch's Autumn Giant being very fine with him at Clumber this season. Another good autumn Cauliflower is Eclipse, a new variety, equal in every respect to Autumn Giant. The produce of seed of it sown here at the same time as that of Autumn Giant was fit for use a month before that variety; the heads, too, were very large and close. Both varieties have done remarkably well with us this season.—G. SUMMERS, *Sundbeck Park*.

Magnum Bonum Potato.—I am pleased to state that my prognostications regarding this Potato have not been verified. Part of the crop has been left out in the ground till the present time (Nov. 15), for the sake of experiment, and the disease has not progressed. As I before stated, it appeared early in October, during the mild weather which we had then, and diseased tubers could be found where the stems were most affected; but since that time it has not gone further; the crop must be reckoned a sound one, comparatively speaking. My opinion, however, still is that it owes its immunity from disease to its lateness, to a great extent. The disease began unmistakably, but was apparently arrested by the colder

weather and frosty nights which set in towards the end of October. I cannot say, however, that it is a good sort to eat at this season; but it may improve with keeping. The Champion has been nearly as good as Magnum Bonum, but the crop was less, and the much-lauded Grampian has turned out a complete mass of rottenness—the worst in the garden.—J. S. W.

Magnum Bonum and Champion Potatoes in Durham.—Champion is this year extensively grown by farmers in this district, and has proved itself to be as good as any other variety, which is all that can be said of it. Many ploughed them up and had them pitted under the impression that they were not diseased; but I could point out instances in which the plague had already put its stamp on the haulm, and, where this took place, sound tubers will be the exception when the pit is opened. Champion is selling very well in the markets, but I can discover nothing remarkable about its quality which is not beyond mediocrity. I have only seen one batch of Magnum Bonum, which was planted on a piece of land that had been a Strawberry quarter for probably twenty years. This was trenched in April, and the bottom of the trench was filled with vegetable refuse; the land was afterwards lightly forked over, and a good dressing of burnt refuse was worked into it, the Potatoes being planted at the same time. They were lifted in the first week of September, and were certainly a fair crop, but nothing extraordinary; while, as regards quality—and they were cooked in various ways—it was as bad as it could possibly be. As, however, they were not at all diseased when lifted, either in the haulm or tubers, they will, perhaps, keep, and may turn out better after a while.—TYNEDALE.

Growing Potatoes on Slopes.—The almost universal method of growing Potatoes is on the ridge system, comparatively few neglecting to earth up more or less. The ridge is of value as a part protection from disease, a sharp, well defined ridge throwing off the rainfall into the furrows, and it is just the reverse when it is so imperfectly formed that it leaves a basin around the stems of the plants. It has been recommended as a preventive of disease to allow sufficient room between the rows for the haulm all to be laid one way, and covered with earth, so that instead of the plants standing out of the top of the ridge they project from the side, the haulm in no way covering the ridge wherein are the young tubers. It may well be a matter of opinion whether the disease is stayed in this way, but all experience favours the plan, as it tends to check exuberant growth, and also the progress of the Peronospora down the stalks of the plant. The plan of planting on the slope is thus explained—The ground to be planted is marked out with a hue into widths of 4 ft., and, instead of being thrown up to a ridge of even sides, is thrown up with a 3 ft. slope to the sun, and a short slope of 1 ft. on the other side. When the tubers are planted, a drill is drawn with a hoe down the centre of the 3-ft. slope, and, as the haulm grows, earth from the higher side is gently laid against it on that side only. A second and third earthing still on the one side is given, and thus there is presently a sharp ridge of earth quite 9 in. thick above the growing tubers. Thus plenty of air is given, and all portions of the haulm are kept from contact with the ridge of soil.—A. D.

The Best Potatoes.—Among the great variety of new Potatoes many are puzzled to select; but Mr. Peter McKinlay, the well-known and most successful Potato grower and raiser, told me the other day that he believed that Woodstock Kidney, taking it in all ways, is the best Potato in cultivation, and the one which he would take with him to a Potatoless island if he were allowed one kind only; but for light and chalky soils he considers the International Kidney almost as well worthy of praise.—V.

GARDEN LABELS.

My friend, Mr. Thos. Williams, does well to direct attention once more to this subject, than which there is none at the present time more worthy of attention. To have a large collection of plants without names is to possess a wilderness. In a good garden every plant should be correctly named, and, if practicable, it should be done legibly but unobtrusively, so that the passer-by may read it if so inclined. We have here over 1000 named Alpines and herbaceous plants, besides hosts of Auriculars, Polyanthus, and other plants, whose names are legion, and every offset of which has to be kept true to name; and so it is evident that permanent labels, easily written and cheaply made, are essentials. We have tried every sort we could hear of. At first we relied upon Maw's terra-cotta labels, but they were failures; the names wear off them, whether written with special pencils or upon paint, and last winter they broke off short by hundreds; so we have abandoned them for ever. The cheap-made pegs, sold in bundles at seed shops, rot off in a year. Prepared paper labels get flabby and dirty, although they do well

for greenhouse purposes, especially for Azaleas, &c.; and, in fact, every sort has failed in practice here but zinc.

Now the zinc label, written with the indelible ink, is almost perfect, and so we have adopted it finally. It is dear to buy in prepared bundles, and none of the shapes sold are good ones; but any iron-monger or tinman will cut up a sheet of zinc into the size required. We use No. 8 zinc gauge, cut into pegs $6\frac{1}{2}$ in. by 1 in. This is a good large size, affording room for large writing. We had a sheet of zinc cut up into this size last week, and were charged 4d. per lb. for the pegs produced; and this is just seven for 1d., which is cheap enough.

The ink we use is as follows, viz., verdigris, $\frac{1}{2}$ oz.; sal ammoniac, $\frac{1}{2}$ oz.; fine lampblack, $\frac{1}{2}$ oz.; good vinegar, $\frac{1}{2}$ pint. Mix thoroughly. A quill pen only should be used. A $\frac{1}{2}$ -pint bottle of it is supplied by our village chemist for 9d. Of course, Yeats' ink is quite suitable, but used in quantity it is too expensive.

In addition to the full name written legibly in ink, we add our catalogue number punched with a steel die. For this purpose we have a set of alphabet dies and of numerals. They cost about 15s. for both sets. It is easy with these to mark every peg permanently, without writing, by using either numerals for references to the catalogue, or by initial letters. For instance, the Aquilegias would have "A." for Aquilegia, and below it, say "G." for glandulosa, or "S." for Skinneri, and so forth, so that you could tell at once the sort. When both punched markings and written are used, the gardener, in taking off the offsets, marks them with the punched marks only on smaller zinc pegs for the store garden; and so the system works well throughout. All our Auriculars, &c., are numbered merely on small zinc pegs by punches, and we find that these are always legible and clear.

I think Mr. Williams' combination peg of wood and wire will be found too troublesome in practice. The label would fall off frequently, and in other ways wood and iron would destroy each other. For a person with abundant leisure the trouble would be of little moment, but I am satisfied that it would not suit me.

BROCKHURST.

— I dislike labels of any kind, especially among rockwork, and if I could trust to my memory I would dispense with them. As this is impossible, I hide them as much as I can under the foliage, or by a stone, thrusting them deeply into the soil and leaving only a couple of inches projecting. To overcome the difficulty caused by labels being lifted out of the ground by frost, and the consequent confusion, make the labels long, at least 9 in. Any one disposed to go to a little trouble to make a good label, which will last many years, may proceed as follows:—Procure pieces of good white deal about $\frac{1}{2}$ in. in breadth; cut them into length of 9 in. or 10 in.; point one end, and char that portion which is to be in the ground; paint the other end, and write the name on while the paint is wet. Lastly, when quite dry, cover the paint with a coat of good wood varnish. In winter days I used to look round to see what labels were required, write the names down on paper, and produce the finished article at leisure in the evenings. I have many such labels now, and indeed many of them have lasted longer than the plants. By adopting a contracted system of nomenclature, and writing from the head instead of from the point, a much less portion than usual may project above the ground—e.g., *Saxifraga pyramidalis* might be written Sax. pyr.—EDWIN JACKSON, *Llandegai*.

— Having used zinc labels for many years, I can speak with confidence as to their durability. The combination of wood and wire recommended by Mr. Williams (p. 445) does not prevent the decay of the wood, though it may delay it. Zinc tallies, on the other hand, are absolutely indestructible; the writing is never effaced, and frost does not throw them out of the ground. They should not be less than 9 in. in length, the width being according to taste. They can readily be made by any tinsmith. Those of a large size for the open ground, 9 in. \times $\frac{3}{4}$ in., cost me 3s. per 100, weight $6\frac{1}{2}$ lbs.; a smaller size for pots, $6\frac{1}{4}$ in. \times $\frac{3}{8}$ in., cost 2s. per 100. Ink, which should be got from a chemist, is composed of 14 grs. chloride of platinum in 1 oz. distilled water. This quantity will last for years. Either quill or steel pens may be used. Before writing, however, the surface of the zinc should be rubbed with emery paper, which may be done at the time of being made, to save trouble when about to be used. I have tried crockery-ware labels; they were continually getting broken, or the names becoming obliterated by the action of the weather. Wooden ones were only a source of worry, and constantly requiring to be renewed. With zinc, however, one's troubles are at an end.—P. NEILL FRASER, *Rockville, Murrayfield, Edinburgh*.

OUR readers will greatly oblige the Editor by sending any sketches of objects which would be interesting or instructive to engrave, particularly views of beautiful plants, trees, or good landscape gardening, or picturesque effects in planting or grouping.

AMONG SUMMER-LEAFING TREES IN SPRING.

GREATER beauty than that produced by a variety of summer-leaving trees in spring could hardly, perhaps, be desired, and such is that shown in our illustration—part of the garden of the Petit Trianon at Versailles. In early summer it is delightful to see the variety of blossom and bud from great wild Cherry trees covered with snowy blossoms to clouds of the delicate tassels of *Acer Negundo*; but among such trees there may in the gardening of the future be developed a beautiful variety of flower life, independent of the trees. Evergreens take possession of the ground almost wholly, and much vegetation under their leaves cannot be, but many of the summer-leaving trees allow the sun to comfort the surface of the earth under their branches for a long time during winter and spring-time, quite sufficient for many of the little hardy flowers of the northern world to bloom and ripen their leaves; therefore in such positions, on many a lawn and in many a park, a beautiful little wild garden might be made of such spring-flowering bulbs, and little plants as the

fresh for any length of time. The plan can be tried on a small scale by inverting a tumbler over a Rose-bud in a saucer of water.

THE LIBRARY.

THE ASCENT OF THE MATTERHORN.*

THIS book is very remarkable for the beauty of its engravings, and though it contains little that interests our readers so as to justify a lengthy notice of it in *THE GARDEN*, the following allusions to the plants that grow on the very highest part of the Alps may be interesting to cultivators of Alpine plants and flowers:

"Those which I collected were as follow:—*Myosotis alpestris*, Gm.; *Veronica alpina*, L.; *Linaria alpina*, M.; *Gentiana bavarica*, L.; *Thlaspi rotundifolium*, Gaud.; *Silene acaulis*, L. (?); *Potentilla*, sp.; *Saxifraga*, sp.; *Saxifraga muscoides*, Wulf. I am

Among Summer-leaving Trees in Spring

Canadian Blood-root and the Golden Aconite. Such spots need not, of course, be mown, as the open bare parts of the lawn must be. Springing up on the Grass, or Moss, or even on the bare ground, such plants would be more beautiful than any common border. Occasionally little plants could be grown in this way that would not thrive anywhere else perhaps. We remember seeing once the little two-leaved Lily-of-the-Valley, a plant seldom seen in gardens, doing beautifully under some Beech trees, and adorning ground that would be otherwise quite bare.

How to Keep Flowers Fresh.—Flowers may be preserved in a fresh state for a considerable time by keeping them in a moist atmosphere. This can be done in sitting-rooms as follows: Pour water into a flat porcelain or glass dish. Set a vase of flowers in the dish, and over it place a bell-glass with its rim in the water. The air which surrounds the flowers, being confined beneath the bell-glass, is kept continually moist with the water which rises in the form of vapour. This is the way in which the late Prof. Lindley used to keep blooms of rare plants which he wished to preserve

indebted for these names to Mr. William Carruthers, of the British Museum. These plants ranged from about 10,500 ft. to a little below 13,000 ft., and are the highest which I have seen anywhere in the Alps. Several times this number of species might be collected, I have no doubt, within these limits. I was not endeavouring to make a flora of the Matterhorn, but to obtain those plants which attained the greatest height. Very few Lichens are seen on the highest part of this mountain; their rarity is due, doubtless, to the constant disintegration of the rocks, and the consequent exposure of fresh surfaces. *Silene acaulis* was the highest plant found by De Saussure on his travels in the Alps. He mentions (§ 2018) that he found a tuft "near the place where I slept on my return (from the ascent of Mont Blanc), about 1780 toises (11,388 ft.) above the level of the sea."

"Mr. William Matthews and Mr. Charles Packe, who have botanised respectively for many years in the Alps and Pyrenees, have favoured me with the names of the highest plants that they have obtained upon their excursions. Their lists, although not extensive,

* "The Ascent of the Matterhorn." By Edward Whymper. London: John Murray.

are interesting as showing the extreme limits attained by some of the hardiest of Alpine plants. Those mentioned by Mr. Matthews are *Campanula cenisia* (on the Grivola, 12,047 ft.); *Saxifraga bryoides* and *Androsace glacialis* (on the summits of Mont Emilius, 11,677, and the Rutor, 11,480); *Ranunculus glacialis*, *Armeria alpina*, and *Pyrethrum alpinum* (on Monte Viso, from 10,000 ft. to 10,500 ft.); *Thlaspi rotundifolium* and *Saxifraga biflora* (Monte Viso, about 9,500 ft.); and *Campanula rotundifolia* (?), *Artemisia spicata* (Wulf), *Aronicum Doronicum*, and *Petrocallis pyrenaica* (Col de Seylières, 9,247).

Mr. Packe obtained, on or close to the summit of the Pic de Malahacen, Sierra Nevada, of Granada (11,600 ft. to 11,700 ft.), *Papaver alpinum* (var. *pyrenaicum*), *Artemisia nevadensis* (used for giving the flavour to the Manzanilla sherry), *Viola nevadensis*, *Galium pyrenaicum*, *Trisetum glaciale*, *Festuca Clementei*, *Saxifraga Grœnlandica* (var. *Mista*), *Erigeron alpinum* (var. *glaciale*), and *Arenaria tetraquetra*. On the Picacho de Veleta (11,440 ft.), and on the Alcazaba (11,350), the same plants were obtained, with the exception of the first named. At a height of 11,150 ft. on these mountains he also collected *Ptilotrichum purpureum*, *Lepidium stylatum*, and *Biscutella saxatilis*; and, at 10,000 ft., *Alyssum spicatum* and *Sideritis scordioides*. Mr. Packe mentions the following plants as occurring at 9,000 ft. to 10,000 ft. in the Pyrenees:—*Cerastium latifolium*, *Draba Wahlenbergi*, *Hutchinsia alpina*, *Linaria alpina*, *Oxyria reniformis*, *Ranunculus glacialis*, *Saxifraga nervosa*, *S. oppositifolia*, *S. Grœnlandica*, *Statice Armeria*, *Veronica alpina*.

"Information on the botany of the Val Tournanche is contained in the little pamphlet by the late Canon G. Carrel, entitled "La Vallée de Valtorrenche en 1867," and a list of the plants which have hitherto been collected on the glacier-surrounded ridge (Fargen Grat) connecting the Matterhorn with the Col Théodule, will be found in Dollfus-Ansset's "Matériaux pour l'étude des Glaciers," vol. viii., part first, 1868. In the "Jahrbuch" for 1873 of the Swiss Alpine Club it is stated that on an ascent of the Finsteraarhorn (14,106 ft.) the following were collected within the last 1,000 ft.:—*Saxifraga bryoides*, *S. muscoides*, *Achillea atrata*, and *Ranunculus glacialis*."

The book is beautifully printed by Messrs. Clowes, and the matter is not without interest, but the style is occasionally undignified and jerky, and not always clear.

WATER FOR NOTHING.*

SUCH is the title of a most interesting little pamphlet on water supply, written by Mr. Shirley Hibberd. The author's object is to demonstrate to the householder that he may, by utilising the rain water that falls from the roof of his house (which is now wasted) be quite independent of the Water Companies. There being always a certain amount of dust and blacks on the tops of our houses, more especially in London, Mr. Hibberd suggests that the first supply of water from the roof should be either rejected or used only for rough purposes, but after "the first flush of the storm the water that follows will be comparatively pure, and will improve by subsidence." The greater part of the water having been obtained, the best of it should be stored in a cool place, and in complete darkness, but a current of air should be allowed to pass over the surface. The water should be kept in tanks, and those made of galvanised iron are recommended by the author as being the cheapest, most wholesome, and enduring of any. In a slate country slate tanks could be used, and would be found to be both wholesome and cheap, while in a timber country wood would no doubt have the preference. Sufficient tank room should be obtained so that the water caught in a wet season may be used at a time when water is scarce. The best water should be passed through a filter before being supplied to the table. In order to save the rain water a Percolator has been proved to be all that can be desired, and the author thus describes it:—"The Percolator is a kind of box with two chambers, as it is fitted into the stack pipe, on a swivel or pivot. A slight shower causes no action of the apparatus, and consequently the water that runs from the roof is lost, or goes into the waste storage. But a rain of some duration brings the apparatus into play. In the first instance, the water from the roof passes through one of the chambers as waste. After from ten to fifteen minutes the second chamber, which is larger than the first, becomes filled with water through the action of a perforation provided for the purpose, and its weight causes it to overbalance the smaller chamber, and the whole affair then moves on the swivel, and the outflow takes a new direction into a pipe which conveys the water to the proper storage for supply of the household. The apparatus requires no attention, for its action is purely mechanical, not a drop of water being able to reach the storage until the rain has continued from ten to fifteen

* Effingham Wilson, Royal Exchange.

minutes. The result is water saved from a well-washed roof and a well-washed atmosphere; and a clean slate roof is as good a watershed as can be desired." Referring to the subject of sewage, Mr. Hibberd very properly states that "Its present unmanageable bulk is wholly due to the admixture with it of the rainfall, which ought to be caught and reserved for many uses, and the remainder guided into channels apart from the sewage." With regard to small houses the primary principle of separating the bad from the good rain-water may be fairly carried out by means of a couple of water-butts, care being taken to get rid of any sediment periodically. The very best roof materials for water-catching are slate and glass, and the author observes of the latter that it is probable it will soon come into use as a substitute for tiles and slates. It is important to convince mankind that rain-water is better than spring, well, or river-water, from the fact that it has not come in contact with the earth. The author concludes his valuable contribution to this now important question by the following remark:—"If the value of pure water for every day use does not appear a sufficient argument for the storage of rain-water, the need of water for the extinction of fire may be urged; for, as the case stands, there is never anywhere a sufficient body of water to render suitable engines and willing hands promptly effectual in extinguishing fires."

ROSES.

PEDIGREE SEEDLING ROSES.

MR. BENNETT, of Stapleford, Salisbury, having shown examples of his Pedigree Roses in fruit the other day, at South Kensington, renewed interest has been excited regarding them. The following is Mr. Bennett's account of the way in which they have been produced:—"In the year 1865 (he says) I began to make the Rose a special study, and noticing that little progress was being made in its improvement, it occurred to me that by judicious cross-breeding some advance was possible. I commenced in 1868 a series of experiments which space will not allow me to enumerate otherwise than to state that they were complete failures. After operating on thousands of blooms I obtained only a very few unripened seeds; these, it is true, gave some distinct flowers, but were of such weak constitutions that they were useless. I continued these experiments in the following season with no better success. In that year (1869), in July, I read with interest a lecture delivered at the Manchester Horticultural Congress on the "Improvement of Plants by Selection, Hybridising, and Cross-breeding, having Special Reference to the Hollyhock and the Rose." There appeared to me to be nothing remarkable in this address; but what surprised me was the remark that the lecturer supposed himself treading in the path of clever men who had preceded him. After detailing some of his experiments with the Hollyhock, he stated: "With the Rose the case was somewhat different. It had been experimented on by clever and industrious men in France for a number of years, and doubtless I was here traversing ground which some of them had exhausted long before." This remark at first somewhat discouraged me. I had fancied there was some unexplored land to be brought into cultivation, and although I knew well that such men as Victor Verdier and Vibert had produced some novelties by artificial means, still I thought that there might be a little ground left unbroken, as all the new Roses which we were receiving from France appeared only varieties of types that had been introduced for years before of either Teas or Hybrid Perpetuals.

Knowing that perseverance is often rewarded by success, I felt inclined to continue my experiments, but to make sure I was not walking in the footsteps of others, I decided to visit all the principal nurseries of the French raisers. In 1870 and the two following years I carefully inspected the Rose nurseries of Lyons, which may truly be said to be the home of the Rose, but I failed to detect any scientific means of raising Roses by an artificial process, and on learning from my much-esteemed friend, M. Jean Sisley, that he had in vain been trying to induce the Rose raisers at Lyons to resort to manual fecundation, I could see plainly that Rose raising in France was like cattle breeding in Mexico, or horse breeding in the New Forest (and I think this remark may be applied to most of the raisers in this country), simply leaving Nature to herself and selecting the best of her produce. From this reasoning I felt certain there was a wide scope for working out fresh ideas, and the greatest difficulty would be to produce good well-ripened seed. Previous experience had taught me that our common open-air method had proved a failure, and was in no way practicable, and that a fresh move must be made. I then tried an entirely new mode of culture, and found, as I had anticipated, that good seed could be produced. I must say that many difficulties were met with, but at last I succeeded in seeding from every Rose I tried, and did not fail in any variety I

crossed, no matter how widely the sorts were separated. The Teas crossed freely with the Hybrid Perpetuals, and *vice versa*, and the Mosses crossed freely with each kind.

For my main experiments I took my favourite Teas, *Alba rosea* and *President*, as seed-bearing plants, and from these I have selected the varieties which I am now cultivating, except one, and it will be found that they possess greater perpetuity as regards blooming, greater depth of petal, and that they are altogether different in type from any Roses before seen. My object has been to produce yellow and white Hybrid Perpetuals, and crimson and high-coloured Teas, and I claim to have produced the first yellow Hybrid Perpetual, seeded from a *Victor Verdier* Rose, blended with *Isabella Sprunt* (this is not yet named); and I lay claim to the first real crimson Tea (*Duke of Connaught*), seeded from *President*, crossed with *Louis Van Houtte*. I can guarantee the parentage of each variety. My experiments have been conducted by myself with the greatest care, and, although it is just possible after I had fertilised a bloom that it might have been re-fertilised by insect means (though it is highly improbable), with regard to the seed-bearing parent there could not possibly be a mistake.

Self-interest compels me for the present to keep my *modus operandi* secret. I do not mean the artificial means of fertilisation, as this theory is well known; but I feel certain that no good Tea Rose seed has hitherto been produced in this country, or ever will be

Pedigree Roses, showing variation in fruit—the larger one *Alba rosea*; the smaller, *Devoniensis*.

except by my process. To save repetition in the descriptions of the individual varieties I wish to state that as all are seeded from Tea Roses it will not be advisable to bud them on *Manetti* stocks. They will in all probability in this respect behave in the same way as the *Rose Captain Christy*, but they all grow luxuriantly on the *Dog Rose* and on their own roots. They are all real perpetuals (not in the same way as the common perpetuals, that give a quantity of blooms in the best part of the summer, and then only a few mediocre blooms now and then afterwards), furnishing a regular and constant succession of flowers till the frost sets in. Not one of them has as yet produced a shoot that has not flowered; they have never been attacked by mildew or red rust, and they have resisted 30° of frost last winter in a very open situation without the slightest injury. The colour of each variety is quite novel, unusually clear and bright; the blooms have great substance, and remain a long time without fading, and are grand exhibition flowers."

We have seen blooms of some of the best of these Roses at the *Handsworth* nurseries, and very beautiful they are, being bright and striking in colour, and deliciously scented.

Standard Roses with Leafy Stems.—Two years ago a man brought me some short *Briers* quite studded with side shoots, and in this respect differing considerably from the walking sticks which we generally obtain to plant for standards. A thought struck me which took this shape—Why trim away all that side growth to the injury of the *Briers*? But I shortened the side shoots, and in due time entered buds on the topmost shoot, and

"bided my time." These trees are healthy, vigorous, all that could be desired for their age, and in the past summer they presented a peculiar appearance. By cautious cutting and pinching I have kept the side shoots within bounds, so that none have grown far out; and now they make a kind of green fringe up the stems, and take away the harshness of outline which obtained for standard Roses the profane comparison with mops and brooms. I should probably not have written this note had I not seen Messrs. Lee's fine show of winter bedding plants at South Kensington a few weeks back. Then I noticed some beautiful standard *Ivies* treated precisely as I have treated my standard Roses, a few stem shoots being left to garnish the pillar that supports the head of the tree. Every day we seem to come nearer to Nature in our exercises within the realms of art.—*Gardeners' Magazine*.

ROSE STOCKS.

THE following question is now and then debated amongst Rosarians: Which Roses are preferable—those on their own roots, or those budded on the seedling *Brier*, on cuttings of the *Manetti*, *multiflora*, or other sorts, or those on standard *Briers*? I have long pleaded the cause of Roses on their own roots for amateur's collections, and depreciated standards, which I ironically called broomsticks. I continue to entertain the same opinion, but I must acknowledge that in this matter, as in others, there are, and must be, exceptions. Roses on their own roots are to be preferred, but I confess that there are certain varieties which, being naturally delicate, gain in strength by being grafted on stouter sorts; although, for my own part, I prefer to reject weak kinds, which check improvement. Grafted Roses possess the great inconvenience of emitting suckers from the stocks, because the latter are constantly disposed to free themselves from the graft, the *Manetti* being the worst of all in this respect.

The seedling *Brier* has the advantage of communicating its vigour to the variety grafted on it; therefore it is particularly suitable for the rapid propagation of new varieties, inasmuch as a single bud makes in one year a stout plant, while cuttings take a much longer time. Plants thus raised are also preferable for sending long distances, which those from cuttings raised in a hothouse are not, owing to their being more tender. Besides, the *Brier* accommodates itself to all sorts of soils, while Roses on their own roots are more particular. The wild *Brier*, too, being robust and very hardy, is also more suitable for pot Roses than have to be forced than plants on their own roots.

Although I despise standard Roses as they are usually planted in a border or on the side of a Grass plot, I must admit that they can be used with great advantage amongst shrubs, which hide the stocks (the broomsticks, as I call them), if care is taken to graft with free growing sorts, such as *Maréchal Niel*, *Gloire de Dijon*, *Noisette Lamarque*, *Desprey*, *Aimée Vibert*, and some *Bourbons*. In this case the *Brier* lives by the aid of the stout variety grafted on it, if not checked by inconsiderate pruning, and if its roots are strong enough to struggle with those of the other shrubs with which it is associated. But if for this purpose weak sorts like Teas are used, failure will be the result; therefore I repeat there is no rule without an exception, so in this case, as in other matters, we must be guided by experience.

JEAN SISLEY.

Lyon.

Standard or Half-standard Roses on *Brier* stocks have always a disposition to produce suckers, even when the greatest care is taken at the time of planting to cut the thick, fleshy roots away from which the sucker shoots proceed, and although these growths may be pulled up as often as they push above ground, yet in time they get so troublesome in persistently making their appearance, that it becomes necessary to take up the plants so as more effectually to cut away the parts from which the shoots spring. Where work of this kind has to be performed no time should now be lost in carrying it out, as if done at once the removal will interfere less with their blooming than it would later on. Advantage should be taken of the opportunity thus afforded of digging the ground over more deeply than is possible whilst it was occupied by the roots of the plants, and also of supplying whatever may be needed in the shape of new soil and manure; and where the land is of an over-light nature it will answer for Roses much better if a liberal quantity of marl, or, this wanting, clay is applied. In the case of either being used it should first be spread over the surface, where it will have an opportunity of getting mellowed by the weather, to enable which it will be best to put the material on the surface as it now stands with the Roses in it before taking them up, and when the pulverising is effected, the best way to proceed will be to begin at one end and take up a sufficient number to admit of a good trench being opened, replant-

ing them as the work proceeds. By this means some labour will be saved and there will be the advantage of the ground not being trampled on more than is necessary to solidify the soil sufficiently about the roots as the trees are put in, staking and tying each as the work goes on. Where any additions are intended to be made, the sooner they are got in and planted the better, especially if we should have frost continued for any length of time towards spring, as when this occurs it sometimes keeps on so long that the work cannot be finished until the time comes when the buds have commenced to swell, in which case they cannot be expected to do much in the way of flowering the same season.

Selection of Varieties.—As to the description of Roses that it is advisable to plant, each case will be best ruled by circumstances. Those who hold the exhibition standard of Roses to be the only ones worth cultivating will, as a matter of course, confine their planting to such; but much the greater number of people who grow Roses for ordinary purposes will far better attain that which they want by selecting those that come more correctly under the class of garden Roses, which, although to some extent deficient in the properties required for exhibition, are nevertheless possessed of the free-growing, profuse-flowering habit. It is the lack of these latter qualities that so often ends in disappointment to those who, with little knowledge of Roses, make their selection alone from the flowers they see shown, many of which, even in the most suitable soils, and under skilful management can only be induced to produce very few blooms from a plant in the course of the season. Wherever the district and situation are such as to give a reasonable chance of their doing well, I should advise a good number of the Tea varieties being grown, and when there is no prospect of these thriving in the open ground, vacant places on walls should be filled with these beautiful continuous-blooming kinds that for cutting have no equals. The old blush and crimson Chinas should have a place in every garden; they are among the first in spring to bloom, and equally the latest in autumn. Respecting the varieties that produce flowers fit for exhibition, there are now such numbers in all colours that are free growers that there is not the least necessity for the general cultivator to plant any of the weakly-constituted indifferent-growing sorts.

Description of Stock.—As to selection in regard to the kind of stocks the plants have been worked upon, the nature of the soil should be considered, the Dog Rose doing better in some, Manetti in others; but in good holding Rose soil the Brier usually does best, and where this is the case I should give it the preference. To amateurs who have not had much experience in Rose culture I should strongly urge the planting of dwarfs rather than either standards or half-standards.

T. BAINES.

AMERICAN NOTES

The Foster Peach.—This new variety has proved to be one of the most profitable market Peaches in Western New York, and those who have had large plantations have made handsome profits from it this year. It closely resembles Early Crawford, and has been supposed by some to be identical with that variety. It differs, however, from the Crawford in the sweeter flavour, obvious to any one who tests the two side by side, and by its rather higher colour. We find that both Early and Late Crawford have been sold under the name of Foster.

Thinning Apples.—President Wilder stated in his recent address that in the English market American Apples of good size, fair, and properly packed, commanded fully double the price of those which had not received that care; and that in our own markets Baldwin Apples of a grower who carefully thinned his fruit brought 2 or 3 dols. per barrel, while his neighbours, from trees not thinned, received but 1 dol.

Chinese Pears.—The "Iowa College Quarterly" recommends Chinese Pears as a substitute for the Quince where the latter does not thrive. They are quite unlike our well-known Pears, firm in texture, and will grow freely grafted on the Apple. They are exclusively for culinary purposes, and when cooked are said to exceed the Quince in flavour. Their complete cooking remains to be tested.

Low-branched Lawn Trees.—Is it generally understood that no lawn tree properly managed can be allowed to lose its lower branches? In a general way it is. Many people recognise the importance of this system of treating lawn trees; that is, they recognise it in a limited way. They think a purple Beech should be low, and a sugar or Norway Maple high. On the other hand, the majority probably give little thought to the matter when they come to plant their lawns. Let us consider the question a moment. It would be, perhaps, generally conceded that the most perfectly-grown tree is the one that attains the most pleasing and complete development of its normal or natural habit. But trees, we know, always branch

low under the most favourable conditions; therefore, we are safe in retaining the low-branched form on the lawn. Other considerations likewise favour this treatment. The stem is thus protected from injury, from sun and wind, and the uninteresting naked stems or trunks, often masked imperfectly with shrubbery, are thus done away with entirely. One of the most perfect specimens of any tree I ever saw was a Norway Maple planted on an open lawn, where its contour from ground to summit was one grand sphere of rich green foliage. Surely, in view of such facts, we need not adhere to the old method of training all trees into a naked stem devoid of foliage. There is no lawn tree that is improved by such treatment, and only the exigencies of sidewalk or road can excuse such barbarous treatment in the case of our noblest trees.

Premature Ripening of Apples in America.—The unseasonably warm weather continues, and its evil effects are seen in a good many ways. Apples are rotting on the trees in many places. We find that on sandy soil even the late keeping varieties will not winter as well as on clay or heavy loam. It is not often that we have so much warm weather late in the season as we have had this autumn. Two years ago there was, however, such weather. That year it was difficult to keep Apples; but those who put them up early in cool cellars and saved them till mid-winter, got a good price for them. I think that this can be done this year. The air outside is much warmer than in cellars until quite late, so that early gathering and storing is advisable. There is, besides, a difference on the same tree. Apples in the centre and north sides of trees will be less mature and will keep better than those otherwise situated. In these hot October days some varieties of Apples in full exposure to the sun seem absolutely scorched with the heat. It is possible that even in Western New York we shall have to select northern exposures and rather heavy soil in which to grow Apples that will prove good keepers.

Peaches.—The Washtenaw Pomological Society, in its report, says that on elevated ground the most profitable fruit is the Peach. More bushels are grown to the acre than of Apples, while one bushel of Peaches sells for about as much money as five bushels of Apples. Four continuous crops have been grown, the amount gradually increasing each year with the growth of the trees. The Peach tree bears younger than the Apple. The sorts mentioned are the following: Amsden and Hale in moderate quantity and on dry soil, on account of liability to rot; Troth's Early, Early Crawford, Oldmixon, Late Crawford, Hills' Chili, and Smock. These ripen in succession, a matter more important with Peaches than with fruits which will keep for weeks.

Fruit House.—Mr. Reeves, of Berrien County, stores his fruit for winter in a fruit-house which consists of a cellar under his carriage-house, situated on a hillside, so that the entrance to the fruit-room is on a level with the ground outside. It is lined inside 4 in. from the wall, the space being packed with sawdust, and it is filled in between the joists overhead. The temperature is easily kept near freezing by means of ventilators. The Apples are placed in barrels, and keep almost perfectly. The last shipment was made this year on the 8th of July, and the fruit sold for \$3.25 per bushel.

The Dwarf Catalpa.—Again I am drawn to say something of Catalpas. Their bright green massive foliage so attracts one by its permanent beauty and health at this season, that I shall not excuse myself for reverting to them. This time, however, I wish to note the value and beauty of the dwarf Catalpa (Catalpa Bungei), a perfectly hardy plant of the most shrub-like character. Retaining all the excellence of colour and form pertaining to Catalpa foliage, as well as its autumn permanence, it is yet always a round compact shrub of considerable size. This rounded shape is decidedly formal, and fits it for standing singly by gates or corners of paths, and also unfits it for grouping with other shrubs. A mass of the dwarf Catalpa, however, planted by itself, especially on a side hill beneath the eye of the passer-by, is very effective in autumn, or indeed at any other time of the year. Notwithstanding all these excellent ornamental qualities, the dwarf Catalpa is little used on lawns. Must we attribute this to want of knowledge of its value, or is it mere neglect?

Kew Garden.—This world-renowned establishment, founded and kept up at such expense, appears to be in poor condition in some respects. It is said that the falling of the rafters in the glass structures actually endangers visitors, nor is this rottenness confined to the older houses. Of some which have been built only a few years, the rafters are not only rotten, but they are absolutely dangerous to passers-by. And yet we are told that on a special day 53,000 people visited the garden. What a pity that these rafters could not have been at the first thoroughly and repeatedly soaked with crude petroleum, and then covered with a suitable adhesive paint!

Dolichos japonicus.—This Japan climber is a new plant on the lawn; indeed few have seen its flowers, at least in America. The leaves are large—8 in. in diameter—of a rich green colour, and rounded in a curious three-lobed way. But the wonderful quality possessed by this climber is the extraordinary vigour of its growth. I am simply stating a fact when I say that in several instances within my personal knowledge it has accomplished a growth of 30 ft. in a single season. Surely such vigour and beauty in a climber should fit it for much important work on the lawn, especially for screening piles of stone and other unsightly objects. The *Dolichos japonicus* has proved to be quite hardy. The flowers are said to bloom in long racemes, with purple and white colours intermixed.—*Country Gentleman*.

The Apple Trade in Canada.—A good business continues to be done in shipping winter Apples to England, and it is estimated that between 5,000 and 8,000 barrels will be forwarded this week. Latest sales on the other side were made at about 23s. and 25s. per barrel, some fancy lots it is said going as high as 30s. Winter Apples in car lots here are worth 275 dol. per barrel, one lot of 200 barrels is, however, reported to have been sold at 260 dol. Several buyers from England and Scotland who arrived here a fortnight ago are now travelling through Western Canada making purchases.—*Montreal Star*.

One of our hands remarked to us the other day while we were surveying a field full of new Potatoes, new Turnips, Beets, &c., which were for the most part failures:—"Tell you what it is, these 'sperment' things ain't worth nothing anyhow." It is a truth that testing "novelties" in a large way is a costly business. But gems do crop out now and then, and those who aid in making them known are engaged in a good work.—*Rural New Yorker*.

NOTES OF THE WEEK.

American Bulbous Plants.—Messrs. Woolson & Co., New Jersey, have sent us examples of some of the rare bulbous plants of North America. They were packed in dry soil in cylindrical wooden boxes, and all of them arrived in capital condition, some of the bulbs even emitting tender rootlets, evident proof that such a method of transmitting bulbs long distances is highly satisfactory. Amongst the bulbs were some of *Lilium superbum*, which, in New Jersey, throws up flowering stems over 10 feet in height; also roots of the true *L. Catesbaei*. They also send bulbs of the rare and beautiful *Cooperia pedunculata* and *C. Drummondii*, the only two species of the genus known. Also examples of the new *Amaryllis Treatia*, a pretty species, allied to *A. Atamasco*; *Nemastylis geminiflora*, *Camassia angusta*, various kinds of *Calochortus*, *Lilium*, *Fritillaria*, &c., and a plant of the rare *Anemone deltoidea*, a Colombian species. Messrs. Woolson are doing good work in collecting and distributing, under their true names, the many beautiful hardy plants of North America.

Libonia penrhosiensis.—That well-known *Libonia*, *L. floribunda*, is far surpassed by this beautiful hybrid, both as regards habit, profusion of flower, and brightness of colour. It is largely grown in Mr. Turner's nursery at Slough, and a very pretty effect it has when seen in quantity. Its bright yellow, scarlet-tipped blossoms render it very showy, and make it one of the most useful of plants for greenhouse decoration in autumn and winter. It is quite as easily grown and propagated as *L. floribunda*.

The Fire Thorn.—The Himalayan variety of this well-known cultivated shrub (*Crataegus pyracantha crenulata*) affords a striking instance of the manner in which some plants behave in different situations or localities. A case in point is the fine example of it now in full beauty against one of the walls at Chiswick, which is said to be the variety *crenulata*, and a specimen of the same kind against the walls at Kew, which obstinately refuses to bear even a small crop of berries. Either the nomenclature of these two kinds is at fault, or there are two forms of one variety, the one bearing an abundant crop of berries every season, the other not worth growing except for its deep green foliage, and there are many handsomer foliaged shrubs than it. This is not a solitary instance, for similar examples have been noticed in other gardens. If it could be satisfactorily proved that the crenulate-leaved kind is a shy berrying variety, then intending planters would know which to select, and thereby obviate the disappointment that now often occurs.

Co-operative Gardening is now being recommended. Good co-operative fruit stores in London and all large towns are much to be desired, not to supersede, but rather to augment the supply afforded by shops and fruit salesmen, these being unequal to the task of distribution. America can send us Apples of better quality than those generally produced in our cold and dripping climate, and in almost any quantities; but our distributive system is so imperfect

that much of this bounteous supply of good fruit is kept out of the reach of the poorer classes altogether, and those who do obtain it can only do so at an enormous percentage on prime cost and carriage. Here is a problem which will pay any one to work out thoroughly well.

Australian Apples, although excellent in quality, are, as mentioned last week, seldom seen in our markets, but in the Indian ports and at Singapore the best samples are eagerly bought at prices varying from 4s. to 6s. per dozen. That this should be so in lands where the most delicious of tropical fruits are abundant is all the more remarkable, and shows that a good Apple is a fruit universally appreciated by Europeans all over the world. One would think that when good dessert Apples cost from 2d. to 6d. in Covent Garden it would pay to cultivate more of them on our own land.

Winter Tomatoes.—It was very cheerful the other day at Kensington to see the beautiful colour of the Tomatoes, which, however, appeal most to the epicure. Mr. Gilbert, of Burghley, assures us that the best Tomato for winter work is *Vick's Criterion*, a smooth, round sort with a slightly crimson hue. It holds its flowers well above the foliage in winter, and sets very freely at that season.

Loddington Seedling Apple.—We have to thank Mr. Lewis Killick, of Langley, Maidstone, for fine specimens of this excellent Apple. It is a kind which never fails to produce a crop of fruit in the worst of Apple years, and is a variety which is being largely planted, or rather grafted on trees of other sorts, in Kent. The tree itself ungrafted never attains a very large size, and is therefore especially suitable for small gardens, whilst the fruit for autumn and winter use is all that can be desired in an Apple. We believe trees of it can now be obtained in some of the best fruit tree nurseries.

The Blue Browallia (*B. elata*).—This pretty Peruvian annual is an important plant in the Slough nurseries for furnishing cut flowers throughout the autumn and winter months. Blue flowers being then scarce, this is a capital plant for supplying them, as it is free as regards growth, easily grown, and flowers continuously. It is also equally well adapted for pot culture, and for border decoration in summer.

Effect of the Frost on Chrysanthemums.—The bright days of a week ago, which made the autumnal aspects of the garden and the wood so beautiful, were followed by frosts very severe on garden vegetation, the flowers of the large collection of *Chrysanthemums* in Victoria Park being destroyed, even those protected by canvas and mats. As Mr. McIntyre grows some 3000 plants in pots this is a serious loss to flower-loving people in the east end.

Ceanothus Gloire de Versailles.—This is a very useful shrub for cutting purposes in autumn, as its pretty blue blossoms are so distinct from the generality of other flowers at that season, and are, moreover, borne in great profusion. In Mr. Turner's nursery at Slough there is a fine plant of it against one of the walls, which we saw a few days ago in fine flower. *C. papillosus* and *C. thyrsiflorus* are also planted against the same wall, and they make excellent bushes, and in their flowering seasons are very attractive with their bright azure-blue flowers. These kinds are apparently quite hardy in this position, as they have been planted for several years though unprotected in winter.

The Jalap Plant (*Exogonium Purga*).—There are not many cultivated plants that are of economic value which make showy garden flowers, but the Mexican Jalap Plant is an exception, as its blossoms are really very handsome, being nearly as large as those of the native large-flowered Bindweed (*Convolvulus sepium*), and of a pleasing violet-purple tint. Like the last-mentioned plant it is of twining habit, and looks very pretty when allowed to ramble over other plants. We saw it in flower at Kew a few days ago against the wall of the Economic Plant House. In the more favoured parts of the country it thrives much better than in the open air at Kew; for instance, Mr. Ellacombe has it rambling amongst shrubs, &c., in the wildest manner, and it flowers beautifully in such a position in his garden at Bitton.

Coriaria ruscifolia.—Those who care for beauty of form, apart from all else, might like this New Zealand shrub. It is a distinct plant. The shoots are very graceful, and the small green flowers hang down in long slender racemes. It is in flower in the Temperate house at Kew.

Jasminum didymum.—A mid-winter flowering plant is more valuable than one that flowers at other seasons, a remark which applies to this pretty Jasmine, which is a native of tropical Australia and the Pacific Islands, and which is now flowering in the Palm house at Kew. It is of twining habit, with glossy green trifoliate leaves, from the axils of which are produced long pendulous festoons of white flowers about $\frac{3}{4}$ in. long, and deliciously scented. As a

pillar plant or for training to rafters it will be found a useful subject, and valuable for cutting purposes.

New Double-flowering Primulas.—The new races of these beautiful greenhouse plants that have been raised by Mr. Gilbert, of Burghley, and exhibited by him at South Kensington on Tuesday last, are quite distinct from the ordinary double-flowering kinds, inasmuch as they are of a much stronger constitution and more floriferous, and the flowers are larger and more compact in form, and have a pleasing variation of colour. For general decorative purposes these will be a decided acquisition, and, as well as for cutting from and for button-hole bouquets, they will be found especially useful, as they keep in good condition a long time. We understand that the stock has passed into the hands of Messrs. Osborn & Sons, Fulham, who will be prepared to distribute them shortly.

Arthrotaxus selaginoides.—This singular jointed Yew I used extensively by Messrs. Charles Lee & Son, Hammersmith, for decorative purposes. The Selaginella-like appearance of its forked stems, furnished as they are with deep green scaly leaves arranged in spiral rows, renders it well adapted for the purpose. In Tasmania, its native country, it attains a height of from 10 ft. to 20 ft., but large specimens of it are rarely to be met with in this country. Unfortunately it is not hardy enough for full exposure in our climate, but it requires only a cool greenhouse temperature.

Mexican Salvias.—The appreciation bestowed on the beautiful cut specimens of *Salvia* which Mr. Cannell, of Swanley, brought to the meeting at South Kensington on Tuesday last, well exemplified how really distinct plants, which formerly were generally cultivated, become supplanted by novelties, and thereby rejected from gardens in general, and are only to be found in botanic gardens or in gardens of which that of Sir G. Macleay, at Pendell Court, may be taken as the type. Mr. Cannell's specimens consisted of *S. Bethelli*, a bright coloured and otherwise very fine variety of *S. involucrata*. It has velvety, green, heart-shaped leaves, and racemes of flowers that are $1\frac{1}{2}$ in. long, of a bright rosy pink hue, with the upper lip of the corolla covered with a wool-like substance, and the lower one with a conspicuous spot of white. Another very distinct character is the pink globular cluster of unexpanded flowers surmounting the raceme. From this character its specific name was derived. The other kinds which were shown were *S. ianthina Hoveyi* and *S. splendens Bruanti*. The former is a deep purple flowering kind, very pretty and desirable; the latter a remarkably brilliant coloured form of the well known *S. splendens*, with bloom of the brightest scarlet.

Heterocentrum mexicanum.—This is certainly one of the loveliest of plants which flower at this season. It is an old stove favourite, but so much neglected as not to be often met with. It is one of the prettiest of the Melastomads, and one of the most easily grown. Its flowers, which are of the most delicate rose colour, are arranged in panicles, perhaps 1 ft. long, terminating an erect leafy stem of three or four times that length. The leaves are nearly oval, and, unlike the majority of Melastomads, are feather-veined; their surfaces are thinly clothed with silky adpressed hairs. An upright yet graceful habit allows this plant a place where others could not stand. There is a white variety of it worth having and the most rare. The specific name indicates its native country.

Paullinia thalictrifolia.—We have to thank Mr. Robert Veitch, of Exeter, for flowering specimens of this extremely elegant stove plant, a state in which it is but seldom met with in gardens. The flowers are produced in short axillary racemes, and have small white petals. Though not showy, it is very interesting in a flowering state.

Royal Horticultural Society.—The following are the arrangements decided upon for the meetings, shows, &c., for the year 1880. Fruit and Floral Committees:—Tuesdays, Jan. 13; Feb. 10; March 9, 23; April 13, 27; May 11, 25; June 8, 22; July 13, 27; August 10, 24; Sept. 14; Oct. 12; Nov. 16; Dec. 14. Whit Monday Show, May 16. Great Summer Show, June 8, 9, 10, 11. Artisans' and Cottagers' Show, August 2, Bank Holiday. Conversation, Wednesday, May 26. Evening Fête, July 21. The date of the Rose Show and Exhibition of the Pelargonium Society will be announced hereafter.

READERS will greatly oblige by sending us notes for this column concerning any subjects of current interest—new or rare plants in flower, or the like.

Nerine undulata (p. 446).—To this must be added another late-flowering species, viz., *N. humilis major*, which is quite a gem. Its deep rose, or rather magenta-red flowers, are large and also wavy margined. I consider this to be as good as the earlier scarlet flowered sorts.—MAX LEICHTLIN, *Baden-Baden*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 18.

THE plants exhibited on this occasion were not so numerous as might have been expected, and the almost entire absence of Chrysanthemums, which are now in perfection, was very conspicuous. However, there were many interesting plants shown, the most noteworthy being a small group of choice Orchids from Messrs. Veitch & Sons, Chelsea, including a remarkably fine variety of *Lælia Dayana* named *superba*. Its flowers are of an unusually rich deep plum colour, and very distinct from the ordinary forms. This was deservedly awarded a first-class certificate. In this group were also the new *Cypripedium Spicerianum*, shown and certificated at the last meeting, and exhibited again in order to show the very distinct colour of the upper division of the flower; also *Cattleya fausta superba*, a fine hybrid between *C. exoniensis*, itself a hybrid, and *C. Loddigesi*; it partakes in a remarkable degree of the former plant. *C. Marstersonia* was another hybrid shown. It is the result of a cross between *C. labiata* and *C. Loddigesi*, but very distinct from either. The white-flowered form of *Oncidium ornithorhynchum* and the curious little *Stelis Bruchmülleri* were likewise comprised in the group. From Mr. Bull, Chelsea, came a larger but similar contribution. The collection consisted of Orchids in flower, such as the rarely-to-be-seen *Cymbidium giganteum*, the superb *C. Mastersi*, a panful of the rare *Trichosma suavis* (a charming sweet-scented Orchid allied to *Eria*), the showy *Oncidium Rogersi*, *Lælia autumnalis*, and others. Amongst fine-foliage plants were the very elegant *Macrozamia plumosa* and *M. Denisoni*, and *Kentia australis*, *Areca concinna*, *Thrinax elegantissima*, all handsome Palms, also *Eucephalartos villosus*, and *Lomaria Dalgairnsia*, and the lovely *Tillandsia Lindenii*, the rosy flower-spikes and purple flowers of which enlivened the whole group. A most attractive feature was a fine group of double flowered Primulas raised and exhibited by Mr. R. Gilbert, Burghley. Several dozen plants were staged, comprising four varieties, viz.: *White Lady*, a pure white flowered kind, with pips large and plentifully produced on short stout stalks; *Marchioness of Exeter*, with white flowers streaked with crimson; *A. F. Barron*, similar to the last, but with ground colour of a purplish shade and faintly striped with a darker hue; and *Lord Beaconsfield*, a beautiful kind with flowers of a bright rosy-pink colour. A fine collection of the single flowering kinds came from the Society's gardens at Chiswick. Amongst these were some having unusually brilliant flowers, such as *Chiswick Red* and *rubro-violacea*, both with blossoms of a rich crimson shade, and both were awarded a first class certificate. In the same collection were *Village Maid*, a pure white kind, and several other varieties of the *fimbriata* and the *filicifolia* type, all well grown and exhibited. From Chiswick came also a fine group of *Abutilons*, comprising several of Mr. George's seedlings and other beautiful varieties, such as *Prince of Orange*, *Reine d'Or*, *Boule de Neige*, &c., as well as a tastefully arranged group of fine-foliaged stove and greenhouse plants, and also cut branches of *Crataegus pyracantha crenulata* gathered from the plant, now in full berry, against one of the walls at Chiswick. Messrs. Jackson & Sons, Kingston, contributed a collection of cut blooms of Chrysanthemums, including several of the newer varieties; the majority of the blooms were large and well formed, and exemplified good culture. A large umbel of flowers of the beautiful *Bomarea Carderi* was shown by Mr. Green, from Sir G. Macleay's garden at Pendell Court; as the flowers were of the second crop of bloom this season, they were necessarily smaller, but in this condition they are extremely handsome. Mr. H. Cannell, of the Swanley Nurseries, brought cut flowers of some very beautiful *Salvias*, which, though their types are by no means of recent introduction, are seldom to be met with in cultivation; they consisted of *S. involucrata Bethelli*, *S. splendens Bruanti*, and *S. ianthina Hoveyi*; these are alluded to in another column. Mr. Cannell also showed some new kinds of Chrysanthemums, and a bunch of the original single-flowered species. Mr. R. Dean again exhibited plants of the pretty *Marigold Diadem*, and also a fine *Hose-in-Hose Primrose* with deep orange-coloured blooms. Mr. Roberts, gardener at Gunnersbury Park, sent an unusually fine variety of *Orotoglossum Alexandrae*, the flowers of which were large and beautifully marked; to this example a cultural commendation was awarded. A special vote of thanks was accorded to Mr. H. Bennett, Manor Farm Nursery, Stapleford, Salisbury, for specimens of his pedigree *Roses* bearing seed-pods in various stages of ripening; these are alluded to elsewhere. A fine group of *Cyclamens* was exhibited by Messrs. Sutton & Sons, Reading, all the plants of which were obtained from seeds sown in October last year, thus clearly showing how fine plants of *Cyclamens* may be obtained in a comparatively short space of time.

Fruit.—Some well-grown bunches of *Gros Colmar* Grape were

shown by Mr. Wood, The Gardens, Leybourne Grange, Kent. They were packed in baskets to illustrate Mr. Wood's mode of sending Grapes to market and elsewhere. Examples of Alnwick Seedling Grape were exhibited by Mr. D. P. Bell, Clive House, Alnwick; one bunch was from the original Vine, which was unusually fine both in bunch and berry; another from a Vine of the seedling grafted on a Black Hamburgh stock; the berries of this bunch were somewhat small. It was stated that 60 lb. of fruit had been produced this season by a Vine of this variety, which was planted in May, 1877. Mr. Sage, Ashridge Park, Berkhamsted, sent a dish of *Vicomtesse Héricart de Thury* Strawberry, which, notwithstanding the lateness of the season, was remarkably good. A dish of excellent fruits of *Pitmaston Duchesse* Pear was shown by Mr. Wildsmith from the gardens at Heckfield, where they were grown on a wall with a western aspect. Some seedling Apples and Pears were exhibited, and amongst them a handsome variety of Apple bearing the name of *Jolly Miller* was shown by Messrs. Wood & Ingram, Huntingdon. Mr. J. Chesher, Peterborough, also showed Apples and Pears. A collection of fifty kinds of Apples and Pears was exhibited Mr. S. Ford, Leonardslee, Horsham, which included some well-grown examples.

Vegetables.—One of the most interesting features of the meeting was the competition for the valuable prizes offered by Messrs. Sutton & Sons, Reading. These prizes amounted in value to nearly £50, and consisted of gold, silver, and bronze medals with added money. The competitors were numerous, the entries numbering forty-four, and the classes were very closely contested. Most of the collections contained some excellent examples of skilful culture, though of necessity some of the produce was not so large as otherwise would have been the case in a more favourable season. The best collection of twelve kinds was shown by Mr. G. Neal, gardener to P. Southby, Esq., Bampton, Oxford. It included well-grown examples of *Ayton Castle Leek*, *International Kidney Potato*, *Suttons' King of the Cauliflowers*, *Suttons' Improved Reading Onion*, *Suttons' Matchless Brussels Sprouts*, *Suttons' Improved Dark Red Beet*, *Suttons' Sulham Prize Celery*, *Suttons' Snowball Turnip*, *Hathaway's Excelsior Tomato*, *Spanish Cardoon*, and *Suttons' Student Parsnip*. Mr. G. Muir, Margam Park, South Wales, won the second prize, and the third prize was awarded to Mr. W. Iggulden, Orsett Hall, Romford. There were nine exhibitors in this class. The best dish of *Suttons' Improved Reading Onion* came from Mr. G. Neal, and the next best from Mr. Wildsmith, gardener to Viscount Eversley, Heckfield Place, Winchfield. Seventeen dishes were shown for these prizes. Mr. J. Townsend, gardener to Mr. P. McKinlay, took the first prize for *Suttons' Woodstock Kidney Potato*; and the second was won by Mr. H. Harris, Denne Park, Horsham. The tubers shown were excellent in every point, but there were but five dishes shown. In the class for *Suttons' Magnum Bonum* there were sixteen exhibitors. The best dish came from Mr. J. Fairweather, Halston, Oswestry; and Mr. J. Richardson took the second prize. Messrs. Sutton & Sons exhibited samples of *Magnum Bonum*, a variety which has resisted the disease, and for the introduction of which, as our readers are aware, the public are indebted to the Reading firm. A collection of fifty-four of the best and most distinct kinds of Potatoes was also exhibited by Messrs. Sutton. Mr. P. McKinlay, Penge, also showed fifty-four kinds, which were all remarkably well grown. Messrs. Carter & Co., High Holborn, exhibited a sample of their *Improved Magnum Bonum* and *Scotch Champion*, both reputedly disease-resisting sorts; also fifty-four dishes of American-grown Potatoes, which have just arrived, and about three dozen dishes of English-grown varieties. The same firm also contributed an interesting collection of sixty-two varieties of Turnips and Swedes which were grown in their trial grounds at Forest Hill. Samples of a very fine sort of Brussels Sprouts were exhibited by Messrs. R. P. Ker & Sons, Aigburth Nurseries, Liverpool. These were remarkably prolific, and are said to be very hardy.

ROYAL AQUARIUM CHRYSANTHEMUM EXHIBITION.

NOVEMBER 19 AND 20.

The annual show of the Borough of Hackney Chrysanthemum Society was held at the Royal Aquarium, Westminster, on Wednesday and Thursday last. The show was in every respect an excellent one, and comprised numerous examples of skilful culture. The classes on the whole were well filled, and in the majority of instances closely contested. In the premier class for the best group staged for general effect there were but four exhibitors. The first prize, consisting of a silver cup, was taken by Mr. J. Balaam, Clapton, who had a collection of well-grown plants comprising several standards; amongst these were fine examples of Mrs. Dixon, Julie L'argraveré, George Glenny, Mrs. G. Rundle, Mr. Brunlees, Brilliant, Faust,

Calliope, &c. In the next class for six standards, the first place was taken with handsome plants of the *Cossack*, Mrs. G. Rundle, Mrs. Dixon, Mr. G. Glenny, Elaine, and Mrs. Haliburton. These half-a-dozen constituted the best plants in the show; in fact, such excellent specimens are seldom met with; they were shown by Mr. W. Brett, gardener, The Cranmers Mitcham. The other classes for pot plants did not include many plants worthy of special comment. The cut blooms were unusually good. The best twenty-four blooms of the incurved section were shown by Mr. G. Langdon, gardener, Brook House, Clapton. The finest of these were *Prince Alfred*, *White Globe*, *Queen of England*, *John Salter*, *Princess Teck*, *Barbara*, *White Venus*, *Golden Beverley*, *Nil Desperandum*, *Hero of Stoke Newington*, Mrs. G. Rundle, *Lady Hardinge*, and others. In the next class for a dozen blooms there were nine exhibitors. Mr. G. Langdon was first with a capital lot comprising fine blooms of the leading varieties. For the class for six blooms there were some fine examples shown by eight exhibitors. Mr. Williams, Stoke Newington, took the first prize with *Yellow Beverley*, *Venus*, *White Venus*, *Barbara*, Mr. G. Glenny, and *Princess Teck*. The next three classes were for amateurs within the Society's districts, but the stands contained not many remarkable flowers. The silver cup for twenty-four incurved blooms was awarded to Mr. C. Sanderson, Willesden, who showed some excellent blooms of *John Salter*, *Yellow Beverley*, *White Globe*, Mrs. G. Rundle, *Prince of Wales*, *James Salter*, Mr. Brunlees, *Princess of Wales*, &c. There were seven competitors in this class. The next three classes were for twelve and six incurved blossoms, and in each the exhibitors were somewhat numerous. There was only one exhibitor in the class for twelve large *Anemone*-flowered varieties, and five in the next class for bunches of three blooms of each variety. The Japanese kinds were admirably shown, and the class closely contested. The first prize collection consisted of *Meg Merrilees*, *Red Gauntlet*, *Fair Maid of Guernsey*, *Oracle*, *Elaine*, *Sarnia*, *Garnet*, *Gloire de Toulouse*, *Peter the Great*, &c. There were seven competitors in this class. The special prize offered by Messrs. Dixon & Co., Hackney, for twenty-four kinds of the Japanese varieties, was also closely contested. It was won by Mr. E. Beckett, Esher, Surrey, with excellent blooms of *Apollo*, *La Nympe*, *Nuit d'Hiver*, *Gloire de Toulouse*, *La Frisure*, *Peter the Great*, *Album plenum*, *Chang*, *Mons. Crousse*, *Sarnia*, *Fair Maid of Guernsey*, and others. There were three other exhibitors who showed excellent blooms on their stands. There were but two entries for six foliated plants, and those shown were not worthy of special note. In the miscellaneous class, Messrs. Jackson & Son, Kingston, showed cut blooms of Japanese *Chrysanthemums*. Mr. Williams, Holloway, contributed a few groups of foliated plants. Mr. Camell, Swanley, sent cut blooms of various kinds of zonal *Pelargoniums*, and several plants of the very graceful *Prenanthes elegantissima*. Mr. Boller, Kensal New Town, exhibited a collection of *Cacti*, *Agaves*, &c.; and Messrs. Hooper & Co., Covent Garden, sent a tastefully arranged collection of dried Grass, flowers, &c.

FRUIT SHOW AT HEREFORD.

The Woolhope Naturalists' Field Club has lately set about the task of improving the growth of Apples and Pears in Herefordshire. A committee of its members, called the Pomona Committee, is now engaged in bringing out a new edition of "Knight's Herefordshire Pomona." Two parts have already been published, and if the editors should have sufficient support to enable them to carry out the whole of their design, the result will be a work which, in the completeness of the text and the accuracy and beauty of the illustrations, will leave little to be desired. It was under the auspices of the Pomona committee that the late Apple and Pear show was held. In the show the principal prizes were taken by Kentish fruit, and chiefly by fruit shown by one exhibitor, Mr. Haycock, gardener to Mr. R. Pemberton Leigh, of Maidstone, who, in the amateur class, took all the first prizes but one, and in the free class eight first prizes out of twenty, and two second prizes. Another Kent exhibitor, Mr. Killick, of Maidstone, also took the first prize in the professional class (nurserymen or market gardeners) for an admirable collection of culinary Apples, which comprised splendid specimens of the following varieties:—*Mère de Menage*, *Lord Suffield*, *Bedfordshire Foundling*, *Loddington* or *Stone's Apple*, *Peasgood's Nonesuch*, *Lord Derby*, *Cox's Pomona*, *Warner's King*, and *Tower of Glamis*. Mr. Haycock's collection of dessert Apples included the *Old and White Nonpareil*, *Duchess of Oldenburg*, *Sykehouse Russet*, *Cox's Orange Pippin*, *King of the Pippins*, *Ribston*, *Reinette de Canada*, *Golden Reinette*, *Summer Golden Pippin*, *Ashmead Kernel*, *Golden Knob*, *Mannington Pearmain*, and other varieties; and his collection of culinary sorts, *Lord Suffield*, *Peasgood's Nonesuch*, *Calville Blanc*, *Golden Spire*, *Small's Admirable*, *Lord Derby*, *Warner's King*, *Dumelow's Seedling*, *Belle Duboise*, *Alexander*, *Bedfordshire Foundling*, *Manks Codling*, *Ecklinville Seedling*,

Northern Greening, Cox's Pomona, Hawthornden, and Hanwell Souring. In the free class for single plates of fruit, Mr. Haycock obtained the first prize for culinary Apples with six specimens of Belle Duboise, which weighed nearly a pound apiece; and first prizes in the class for Ribstons, Nonpareil, Russets, and Lady's Finger. Mr. Haycock's show of Pears was very fine, but Sir Henry Scudamore Stanhope ran him closely with an excellent collection from the famous cordon wall at Holme Lacey, upon which—as Sir Henry tells us in the second part of the "New Pomona"—within a space of 37 yards in length eighty-three Pear trees are trained, comprising forty-three varieties. As we are chiefly concerned with the commercial aspect of fruit growing, whether for domestic consumption or for other purposes, we do not propose to draw any conclusions from the show of dessert Pears, in which the collection was extremely rich, the best specimens in our judgment being in the collection of fruit grown in France, which contained also some fine examples of culinary and dessert Apples. No doubt the choicest sorts of Pears may, in favourable seasons, be produced in this country by private growers, as the collection showed by Mr. Haycock and Sir Henry Scudamore Stanhope testify, the weather notwithstanding; but in the market the English grower will, as a rule, be unable to stand against the importation from France and Jersey. Indeed, we understand that Mr. Haycock himself admitted at Hereford that, while he could beat all England, Jersey and France could always beat him.

ANSWERS TO CORRESPONDENTS.

Soil for Ferns.—*J. M.*—The robust-growing varieties of hardy Ferns thrive best in two-thirds fibrous loam and one-third peat and leaf-mould in equal proportions. Lastreas, Scolopendriums, Athyriums, Polystichums, &c., grow all the more vigorously when top-dressed with a little thoroughly rotten manure. The smaller growing species, such as Asplenium Trichomanes, A. septentrionale, &c., prefer a fibrous peaty soil; in many instances an admixture of pieces of sandstone will be found beneficial. Where any doubt exists as to the nature of the soil required, employ peat, as all kinds of Ferns will flourish in that compost, although, as before stated, the major portion of the hardy kinds prefer stronger food.—*B.*

The Cardinal-flower.—*Alpha.*—The varieties of the herbaceous Lobelia, of which *L. cardinalis* is one, should be treated as half-hardy plants; they should be lifted and wintered in a cold frame, which should have the protection of some covering in severe weather. Spring is the best time for propagating them, when the plants have pushed a few inches; the roots are then either divided, or the shoots taken off at the base and struck in gentle warmth.—*A.*

Peach Trees.—*A. B. C.*—Peach trees planted at the back of a lean-to Vinery, in which the Vines have reached the top of the house, will not do much good; but you need not be afraid that they will injure the Vines.

Covering Vine Borders.—*Subscriber.*—Sheets of thin corrugated iron would be suitable for covering Vine borders in winter, but they should also have litter under them. The sooner now they are covered the better.

Evergreen Climbing Roses.—*Rosa.*—These require but little pruning. If the plants are young, shorten back the shoots slightly in March, and train so as to cover the wall or trellis in the desired manner. In the case of old specimens, the weak growths may be cut out so as to allow the strong shoots to mature—thus enabling the plants to produce flowers of better quality than could be the case were the wood allowed to become so thick as to exclude sun and air.—*J. C.*

Sowing Seeds of Araucaria.—*P.*—Having well-drained some pans or boxes, fill them to within 1 in. of the rim with two-thirds leaf-mould and one-third loam, adding to the whole one-sixth of its bulk of silver sand. Insert the seeds in the soil about two-thirds of their length, so that the large end of each seed is not covered. Place the seed-pans in a cold house or frame, water sparingly, and be careful not to let them fall a prey to mice. March is the best time to sow.—*C.*

Drying Fern Leaves.—*Q.*—Fern fronds gathered now may be kept green and fairly fresh for some time if gathered when dry, exposed to the air for a short time to be thoroughly dry, and then laid between double leaves of newspapers, and put away in a cool room. The hardest and toughest fronds, such as those of the *Lastrea Filix-mas* of the hedgerows, also of the *Pteris aquilina* or common Bracken, naturally keep best and longest. When used they should be handled with special care, as the pinnae are tender and liable to injury.—*A.*

Unfruitful Trees.—I have some Apple trees that seem to be too luxuriant to bear. Should they be root-pruned?—*E.* (Yes, if the same tendency to make such growth has been noticed in previous seasons. The way to root-prune has been recently referred to. If the trees are not too large, carefully taking them up and replanting will perhaps be the best way of giving the necessary check, as this affords an opportunity of giving the roots a horizontal direction, and brings them near the surface. Root-pruning merely chops them off without altering their direction.—*E. H.*)

Shallow Orchid Pans.—Where can Orchid pans, such as those used in Messrs. Veitch's nursery, be obtained?—*R. C. APPLETON, Beverley.* [The Orchid pans at Messrs. Veitch's, described in last week's GARDEN (p. 436), were obtained at Matthews' potteries, Weston-super-Mare.]

Names of Plants.—*F. M. J.*—There is no species of *Dracena* bearing the name you mention.—*C. T. D.*—1, Apparently *Polypodium Phymatodes*; 2, *Aspidium coriaceum*; 3, *Scolopendrium vulgare ramosum*.—*R. D. S.*—1, *Lasiandra macrantha*; 2, *Begonia Rex*.—*T. S. W.*—1, *Helicoborus niger major*; 2, *Il. abscissus*.—*Conifers*—1, *Retinospora obtusa* *lycopodioides*; 2, *R. obtusa nana aurea*; 3, *R. obtusa nana compacta*; 4, *R. plumosa aurea*; 5, *R. obtusa nana*.—*Anon*—1, *Veronica decussata elliptica*; 2, too much withered to identify; send good specimen.—*M. C.*—We cannot undertake to name varieties of *Chrysanthemums*; they should be referred to some specialist.—*Orchid*.—*Odontoglossum crispum*.—*D.*—1, *Adiantum reniforme*; 2, *Asplenium ferulaceum*; 3, *A. Hookerianum*; 4, *Davallia Tyermanni*; 5, next week.—*Enquirer*.—1, Berries

of *Solanum Dulcamara*; 2, Berries of *Hippophae rhamnoides*; 3, berries of a species of *Elaeagnus*.—*S. T.*—We cannot name seedling forms of Lawson's Cypress, as they vary so much in a mature state.—*T. (Macedon)*—*Coccoloba platyclada*.—*Enquirer*.—*Dahlia imperialis*, now finely in flower in the Palm-house at Kew.

Names of Fruits.—*R. S.* Pears—1, Forelle; 2, Beurré de Capiaumont; Apple not known.—*H. R. S.*—Pears—1, Brown Beurré; 2, Beurré Superfin, Beurré Bosc.—*M. S. F.*—Apples—2, Cox's Pomona; 3, Duck's Bill; 5, Adam's Pearmain; 6, Cockle's Pippin; others not known.—*S. T.*—1, Cellini; 2, Golden Pippin.—*Herts.*—Pear—Beurré de Capiaumont.—Apples—1, Dumelow's Seedling; 2, Holland Pippin.—*W. T.*—Pear—7, Gansel's Bergamot.—Apple, 9, Dumelow's Seedling.

Questions.

Lettuces under Cloches.—I am trying the French method of growing Lettuces for winter salads under cloches, and should be very glad if any of your correspondents would give me the benefit of their experience of the system, and would also give their opinion why the cloches are so little used in England? We have placed them over young Lettuces planted out early in October; the bed slopes gently upwards towards a brick wall, and has a full south-west exposure. The glasses are tilted up a few inches during the day whenever the weather is not frosty, but I suppose now it is cold enough to keep them down altogether. I shall be very grateful for any hints on the subject.—*MRS. F. RICARDO, The Friary, Old Windsor.*

Boronia megastigma.—How shall I treat this so as to induce it to flower in the spring? The heat of my greenhouse averages 50° at night.—*M. M.*

Carnivorous Plants.—A friend writes to ask us not to be too sudden in our conclusions as to the relations between insectivorous plants and their prey. He points out that the loss of a few individual leaves or pitchers, as so often—indeed, almost invariably—happens in the case of *Drosera dichotoma*, *Sarracenia*, and *Darlingtonia*, when flies are captured by them, is not any proof of their either being injurious or of their not being essential. One must rather observe that plants which capture flies do, in the long run, benefit by them and produce a larger quantity of heavier seeds than those which are unfed either by accident or design. This much careful observation has proved to be the case. It is, of course, granted that all plants have the power of absorbing nutritious substances by their leaf tissues, but *Dionæa*, *Nepenthes*, and other so-called "carnivorous" plants differ in that a digestive fluid allied to Pepsine is secreted by their leafy tissue, and they are thus enabled to disorganise and feed on nutriment designedly brought into contact with them in a more material or solid state than is usually the case. It is admitted that much nonsense has been written on the whole matter, but when Nature makes a beautiful and efficient fly-trap like that of *Dionæa*, and leaves her victims with a copious peptic saliva after they are caught, there can be but little doubt that ultimate benefit is the result actually aimed at and ultimately attained. The whole question is admitted to be one of degree rather than of any marked difference in Nature's plan.

THE annual November soiree given by the Messrs. Sutton to their employes took place at Reading, on the 13th inst., when nearly 300 sat down to dinner. The several tables were presided over by the heads of departments, and at the principal table were Messrs. M. H. Sutton, A. Sutton, M. J. Sutton, A. W. Sutton, and Herbert Sutton. Mr. M. H. Sutton, the senior partner of the firm, in an appropriate speech, expressed the great pleasure which he felt at being able to meet them again this year. He missed, however, he regretted to say, some familiar faces which were wont to be present on former and similar occasions, and who had been removed by death. He spoke of the continued growth of the firm, and attributed such a result to the thorough business habits of the heads of departments, acting in conjunction with the heads of the firm, and to the care that was bestowed in the selections of seeds, for which the establishment had become world-wide famous.

HIGH GROVE, Eastcote, near Pinner, the residence of Sir H. Hume Campbell, Bart., was early on Sunday morning destroyed by fire. The strong room, which contained a large quantity of plate, was the only apartment that escaped. The cause of the fire is at present unknown, but it is attributed to a defective flue. Some fine trees, amongst them a lofty *Salisbury* and a large *Catalpa*, though near the burning building, have sustained, we understand, but little damage.

Remedies for Slugs.—If the readers of THE GARDEN generally are as much troubled with slugs in their gardens as we are, it may be useful to say that the best preventive against their ravages on our rockeries has been a cordon of silver sand put round the rarer plants; but I saw a gardener the other day using cork dust (in which the foreign Grapes come packed) freely. He said it was very effectual, as they evidently could not move over it. Its advantages over sand are lightness and looseness, but, no doubt, from many places it would be removed by the wind; still in sheltered nooks (those in which slugs are numerous) it might be used with advantage.—*JOHN WOOD, Kirkstall.*

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

LETTERS FROM SOUTHERN FRANCE TO A
GENTLEMAN IN ENGLAND.—No. I.

NICE, Nov. 20, 1879.

MY DEAR SQUIRE,—

When you kindly entertained me under your hospitable roof, and under a canopy of clouds which had been suspended, with two or three lucid intervals, for a period of twelve months over your ancestral chimnies, you told me, in the smoke-room, and on the eve of my departure for the Continent, that you considered our English climate to be, on the whole, the most delightful of all, and that, although you did not speak from experience, never having left our Fatherland, you firmly believed that in anticipating fine weather, and fine flowers, and beautiful scenery on the shores of the Mediterranean in November, I was preparing for myself a woeful disappointment. I thought of your warning when, to refresh my spirit in the tedious operations of the razor, I looked next morning from the window of my dressing-room, and saw the water still resting in peaceful patches here and there upon your pastures; your soddened stubbles, which must have yielded you something like three sacks of unwholesome Wheat or discoloured Barley to the acre; the trees in your park, which were unanimously throwing off their raiment, as though about to bathe in the stagnant pools hard by; and, in the gardens below, your Dahlias and Heliotropes blackened by the frost; and your exquisite geometrical design of variegated eels, tricoloured worms, and glowing tadpoles somewhat marred by the removal of a large portion of the plants to their winter quarters, and the disappearance of colour—a few pips of scarlet Pelargonium being honourably excepted—from the rest, and I said to myself, "It may be that my good host is mistaken; it may be that all travellers are not tail-less foxes, who would induce others to separate themselves from the comforts of home as they have; it may be that there are brighter, gayer, drier scenes than this. *Cras ingens iterabimus æquor.* I will go and see." Yes, though like the soldier who would displace his rival the sailor in the affections of the 'artless thing,' Madame Favart, I 'praise the land and blame the sea,' will I brave, nevertheless, all the perils which may confront me between Dover and Calais, all the wearisome journey from one end of France to the other, disdaining the recumbent luxuries of the Wagon or Coupé Lit, and will verify or falsify with the eyes which have read them, the glowing descriptions of the Riviéra.

Permit me, dear friend, to report results to you. Very near the end of the third week in November I am writing by a window wide open in the hot sunshine and under a bright blue sky. We (including delicate ladies quickly susceptible of cold) have just finished in this delicious atmosphere the excellent *café au lait*, &c., which gives the appetite a preliminary canter for the longer course or courses of the *déjeuner* hereafter. I look through the window aforesaid, and I see that huge Cactus, the Prickly Pear, full of fruit, four large specimens on one leaf, and close by a Lantana, with its gay red and yellow flowers, occupies a space about 14 ft. in height by 10 ft. in breadth. Some of the upper branches have left the wall and are drooping over an Orange tree laden with golden fruit. Next to this there is an Arbutus (which ripens its Strawberries so thoroughly here that the tree must no longer

be called Unedo; eat one and you will want no more, because they are good for food, both preserved and *au naturel*)—a great tree full of blossoms; and beside it the Japanese Medlar, also showing abundant promise of fruit.

If I go into the gardens of the hotel I find the *Datura*, with its beautiful white bells; *Roses Lamarque*, *Homère*, *Bourbon Queen*, *Mrs. Bosanquet*, the *Old Monthly*, and other *Chinas*, such as *Fabvier* and *Cramoisis Supérieure*, *Safrano*, *Gloire de Dijon*, &c. (in other gardens I have twice seen *Chromatella* or *Cloth of Gold*); the *Heliotrope* flowers freely and perfumes the air; *Plumbago capensis* covers great bushes with its blue-grey blooms; *Acacias* and *Abutilons* are here in profusion; and there are *Violets* and *Carnations*, *Zinnias* and *Pansies*, *Escallonias* and *Veronicas galore*.

The *Polygalas* and *Chorozemas*, which you English tie out in pots, and coddle under glass, and take to exhibitions, grow here to any size you please; and the *Palms*, which you put on your dinner-table, are great trees 15 ft. high, with their *Dates* hanging down in huge bunches on their long red stalks.

Do you remember a plant of *Bougainvillea glabra*, which you showed me in your stove, proudly pointing to its flowers, few in number, in complexion pale? I saw it yesterday covering a coach-house. It really made me for a few moments feel faint and ill with admiration. A mass of roseate beauty, with a tinge of mauve or blue—all flower (or rather bracts)—scarce a leaf to be seen. The ghost of *William May* must haunt that coach-house, and my heart yearned for *Thomas Baines* and a score of plantmen, who would have shared my happiness.

I have only given you a partial account of the gracious glory of this favoured place. I have said nothing of the mountains, and sea, of the *Olive trees*, *Fig trees*, and *Vines*; but I hope I have demonstrated to your reasoning power that there are more things in heaven and earth than are dreamed of in your chill and cloudy diggings, and that the sun, of whose existence you began to have excusable doubts, has still, when he pleases to show it, his ancient splendour and beneficence.

Accept the assurance of my highest consideration, and believe me to be

Yours ever sincerely,
S. R. H.

ENGLISH AND FRENCH EXHIBITIONS.

THE remarks which I made a few weeks ago on this subject have received so remarkable a confirmation, and that from an unexpected quarter, that I think a reference to the subject may not be out of place or wanting in interest. It may be remembered that I doubted the dictum in this case that "they manage these things better in France," and that the French system would be simply intolerable in this country. In one point I give the palm to them—the artistic arrangement of their exhibits; but I, at the same time, asserted that it led to such hopeless confusion that it would be impossible to carry it out here; but, as will be seen in the sequel, the testimony I quote rather concedes to us the superiority of arrangement. I refer to an article which has lately appeared in the "*Revue Horticole*," by *M. Joly*, Vice-President of the *Société Centrale d'Horticulture de Paris*, a copy of which he has been good enough to send me. I must premise, before referring to it in detail, that my former paper was written without reference to it, and I am sure his was written without any reference to mine, and that no better or more unprejudiced testimony could be given than that of the accomplished author of the paper in question.

M. Joly had attended the exhibitions at *Cologne* in 1875, *Amsterdam* in 1877, *Ghent* in 1878, and, finally, this year came over to *London*, in order to be able to report his experiences to the society of which he is vice-president.

He appears to have been so pleased with his visit that he earnestly urges his compatriots to run over for even a couple of days to *London*. To visit *Covent Garden* in the early morning, then to go to the exhibition at *South Kensington* and the parks; on the following morning to see the marvellous establishments of *Messrs. Veitch* and

Ball; in the afternoon to go to Kew, and return in the evening to Paris; and he thinks that, having got a taste of the horticultural treasures of London, they will, like Oliver Twist, "ask for more." The plan of holding exhibitions for special kinds of flowers finds favour with him, and the large sums of money, medals, &c., offered by the Royal Horticultural Society and the different special societies are evidently a matter of surprise; while I am glad to see that our system of judging is evidently preferred by him to that of the French; and the giving different small bodies of jurors separate portions of the show instead of having a whole mob of jurors going over all the exhibition, is all that is required to make an alteration which would materially improve the character of French exhibitions.

It will, perhaps, surprise those who have heard so much of the parks and promenades of Paris, that while M. Joly applauds without reservation our method of having exhibitions in tents, and desires that it should be imitated in Paris, he says there is no place in that city where such an exhibition could be held as at South Kensington. By-the-bye, he has made one very excusable error in supposing that the gardens belong to Kensington Palace.

In describing the tent at South Kensington, he contrasts it with their arrangement, and here, I think, is the most remarkable part of his paper, and I therefore give it *in extenso*: "With us there is generally made a Grass plot in the centre, with a depression in the middle, and baskets placed round it. On this are placed large plants as single specimens, and round the tent fine-foliaged plants, such as Palms and Rhododendrons, with the inevitable rock in the distance. In London the large tent is arranged differently, and I must say that its appearance is more happy. The ground is depressed in the centre, and raised up all round. Each group forms a terrace with Grassy shelves, on which are placed fine-foliaged plants. The general effect is more favourable. In the middle are placed the small plants, and the boxes containing cut Roses. At Brie Comte Robert, as with us, we are literally inundated with Roses, and the eye has a great difficulty in discriminating between the good and indifferent ones. This year I have seen exhibited in one lot 300 blooms of Jules Margottin; what interest could there be in seeing that? In London the competition is not only between amateurs, or between horticulturists, but with only one or three Roses of each variety; it is not the quantity that is of any consideration, but the quality. There is nothing that can be seen with us like the perfection of culture or size here exhibited. At the exhibition of May 4 last Messrs. Turner and Paul exhibited Roses in pots of the varieties Charles Lawson and Celine Forestier. Each plant, more than two metres in diameter, had nearly 300 Roses equally distributed. It is the same with Dahlias, Grapes, &c.; it is an ordinary thing to see bunches of Grapes exhibited weighing eight to ten kilogrammes. In order to obtain these marvellous results the method of proceeding is always the same; to take away three-fourths of the fruit, or, if you wish, rub off for a truss of Roses nine out of ten to obtain one which may be exceptionally fine."

This testimony is, I think, very valuable, for it concedes to us that which we are continually reminded we do not possess—taste in our arrangement; and, notwithstanding all the outcry that has been made about our formal method of exhibiting Roses and cut flowers, it is looked upon by M. Joly as superior to the huddle-muddle of the French method. He expresses the same admiration of the method of showing Pelargoniums, Fuchsias, and even vegetables, and then enters upon the question as to the value of exhibitions in general, and the best method of improving those in Paris in particular. The great difficulty seems to be the place. The only places that he considers at all appropriate are (1) the grand alley opposite the Exposition des Beaux-arts; (2) the large centre reservoir of the Tuileries; and (3) the grand central alley of the Tuileries gardens, or that wherein the Orange trees are placed. It is to this latter that M. Joly inclines, but while borrowing many ideas from us, he still maintains that, in order to be a success, the exhibits ought to last a week at least; but, in the matter of prizes, he evidently desires to get away from the everlasting medals which constitute the sole rewards in the French exhibitions; and he proposes that professional horticulturists should have the option of medals or money, and that amateurs should have objects of art. He says: "Although these words 'Honneur et la Patrie' may sound very grand, I think that prizes in money would be viewed without disfavour by three-fourths of the exhibitors." He also wishes to see their vegetables exhibited in a better manner, and actually adds that in England we shed a charm of poetry round them by the manner in which we exhibit them; and that exhibitions of fruit trees, as at Amsterdam, and table decorations, as with us, should be encouraged. He would also desire to see the juries differently arranged, and if not paid, as with us, that, at any rate, they should be "fêted," as in Belgium; and, in summing up, adds that this would effect a triple object—maintain their importance as a society, unite on one common ground men devoted to the same

cause, and entertain amicable relations between their own countrymen and strangers.

I cannot but think that many of those who are continually depreciating our efforts on this side of the channel in the matter of horticultural exhibitions may learn a lesson from this remarkable paper, and see that the opinions are not shared by those who are well calculated to judge; and those who undertake the management of our great London exhibitions may take courage from these laudatory remarks of a competent French authority. I have long contended—and oftentimes against a strong contrary opinion—that in the matter of exhibitions, as far as the excellence of plants and flowers are concerned, we are far in advance of our neighbours. It is something not only to have this acknowledged, but to be also assured that in a matter in which they were considered ahead of us we are allowed, at any rate, not to be behind them. DELTA.

LEAFLETS.

MR. J. B. ARMSTRONG, Botanic Garden, Christchurch, New Zealand, sends me some very interesting notes:—"We have in New Zealand many plants of chaste beauty, which would delight your lovers of Alpine plants. For many years past I have spent my spare time in studying and collecting the flora of our Southern Alps—mountains which attain an elevation of 13,000 ft., and where even in the valleys the thermometer is frequently below zero. You will readily see that such a district, and it is of great extent, must contain many plants likely to prove hardy in England; in fact, I am certain that our native sub-alpine shrubs will eventually become the common ornaments of your gardens.

For instance, we have fifty species of Veronica, many *Olearias* superior to the one you have (*O. Haasti*); splendid *Senecios* with leaves as fine as those of a *Rhododendron*, and many others, besides numerous beautiful herbaceous plants. Unfortunately your English cultivators have got into their heads that New Zealand is a hot country, and they not unfrequently kill our natives with too much coddling. It is rather amusing to hear of the sub-alpine Cabbage tree (*Cordyline indivisa*) being shown as it has often been in a collection of stove plants."

Mr. Armstrong also sends me a few seeds of the splendid *Myosotidium nobile*, which, he says, may not unlikely be hardy in England, as it has lately been found on the coast of the coldest portion of the colony, viz., Stewart's Island. It is a seaside plant, and is fond of damp sand, heavily manured with seaweed. It is not difficult to grow, but is a short-lived plant. In New Zealand it produces leaves measuring 18 in. across, and heads of lilac-blue flower 6 in. through. It is a gigantic Forget-me-not.

A correspondent writes:—"I have been at the Liverpool Chrysanthemum Show. The way the plants, fine in themselves, were tied out to sticks as stiff as pokers was sad to see. I had hoped all this horrible formality of training had exploded." Perhaps some good may be done by employers prohibiting this waste of labour, to produce that which is in no way beautiful, but quite harmful in its tendency. The absurd training has not even the merit of producing better flowers.

I wonder to what extent the plague of caterpillars and the swarms of moths, which have been noted everywhere this year, was brought about by the scarcity of birds. It is an undoubted fact that our usual garden birds were destroyed by thousands last winter; and this was probably the real cause of the plague of caterpillars, as their eggs were not consumed as usual by our feathered friends.

Robin Redbreast is the familiar friend of our gardeners, sitting on the potting bench at dinner time, and on the wheelbarrow whilst the digging is going forward in quest of his "grub"; but it does not do to let him spend a night in one's late Vinery this cold weather. He is very fond of Grapes, and will spoil a good many if you will allow him.

A friend of mine, who grows Auriculas largely, tells me that a pair of wrens which frequented his Auricula house during the summer, might be seen daily perching upon the edge of the pots and picking off the green fly from the under sides of the leaves. If we only knew the true use of birds to gardeners we should value their company more highly than some of us at present do.

A correspondent protests against the small plants sent out by our very best florists in execution of orders for Alpine and herbaceous plants. It is the fashion to send out a small thumb-pot with the least scrap of a plant in it. Many north-country tradesmen are now sending out good-sized plants from the open garden, and we fancy a nurseryman's business would be much more easily managed in this way than by keeping his stock in pots. As Alpine plants are becoming popular, it is worth consideration whether the ordinary plan of working the trade cannot be improved.

Referring to Gros Maroc Grape, as noticed in "Leaflets" (p. 432) Dr. Roden tells me that this Grape has been grown by him some fifteen years past, and is a great favourite of his; that it is very handsome both in bunch and berry (the latter oval in shape); that it carries a good bloom, and, as a late keeper, is worthy to associate with Alicante and Lady Downe's Seedling. It is also of good flavour and easy of culture. I note that although Mr. Rivers has it in his collection, it has for some years past been withdrawn from his fruit list, and I have often wondered why?

I hear from a gardening friend, who observes closely, though he does not write much (and consequently avoids "wobbling"), that Sutton's Late Queen Broccoli was, during the last very severe winter, the hardiest of all the Broccoli, and kept the table supplied after all others were killed, till the end of June and beginning of July. He also tells me that Telephone Pea (why not call it "Eureka," for it was discovered in Culverwell's Telegraph), after all the severe criticisms, is really quite distinct from Telegraph, and a much better Pea in every way, and should be grown as a second early.

I read in a "Society" journal that a second batch of 100 Oak trees has been sent by Mr. Parker, of Southgate Place, to a gentleman for planting on Lansdown this year, in support of his principle of cultivating gardens by electrical action, whatever mode of culture that may mean.

Mr. Sadler tells me of the great good which has been effected by the opening of the Edinburgh Garden throughout the day. The public use the garden, and seem to enjoy it to a much greater extent than before. Even when admission was not refused to anyone who rang the bell and asked for it, this slight barrier prevented people from freely entering the gardens as they do now. The work in the houses and out-of-doors is carried on without the slightest inconvenience to the men, and with much less trouble now than used to be taken in the shape of precautions as regards the few that were admitted in past days.

A *propos* of Mr. Williams' remark (p. 445) as to the state of the herbaceous ground at Kew, early in the season, viz., 'that the display of plants was meagre, the most conspicuous

feature being the display of unnecessarily large labels," I may mention that a friend of mine was walking the other day in that part, when her little girl said, "Mamma, do they bury babies here?" The mistake as to locality was certainly excusable, but the labels are not at all so bad as I have seen. In old days in the Botanic Gardens in the Regent's Park, when they had Teak labels 2 ft. long, the difference between the herbaceous department and the Marylebone Cemetery was not so very apparent. At that time Kew had adopted the little iron T label, which looks much better.

I notice men busy trying to fill up the ugly holes and ruts into which the wooden pavement in Piccadilly has lately fallen. It will not be very long before the people will find this pavement impracticable, from its very expensive nature and its want of endurance. It is, besides, the most dangerous pavement in frosty weather, and has other serious drawbacks, one of which is that it absorbs and gives off offensive matter.

So far as I know, the most perfect city street is one made of asphalt, and it would be easy to remove the dust and mud from the streets by employing water freely. Why could not the fire hose and director, numbers of which are now laid down in our City streets, be made use of early in the morning, or late in the evening for cleansing them, where asphalt is laid down, and pavements everywhere? If this were done, all danger to life and limb would be at an end.

In Paris there is a wide difference in price in the different coloured Violets. While common blue Violets, single and double, are fully as cheap as in England, the lilac varieties of the Neapolitan type are, or were early in November, very dear. The former are also offered in small bunches fit for button-holes. The latter are invariably made up into large bouquets, ranging from 4 in. to 1 ft. in diameter.

The Parisian bouquets are mostly far too large. Bunches of Roses 18 in. across in November were not only a great waste of floral beauty, but would also need a strong arm to carry them. Most of the French bouquets are also formed of one kind of flower, and very seldom indeed is more than three varieties used in the same bouquet. Occasionally Roses, Mignonette, and Pansies are used together, but not often.

A very choice All Saints' Eve bouquet was purchased in the Madeleine Flower Market for five francs. It consisted wholly of Orange blossoms, mixed and fringed as was thought with small Orange leaves. On examination it was found that each single blossom was mounted on a stem apparently of Grass or small hard Rush. No ties were used. These stems were sharp at the upper ends, and the single flowers were merely pushed on. The leaves were also found to be not Orange, but a variety of the *Solanum Capsicastrum*. These were no bad substitutes, and with daily sprinkling the bouquet kept fresh and sweet for a week. Surely it was exceptionally late or early for Orange blossoms, even in France.

The flower girls on the Boulevards of Paris—who are not numerous—have an odd way of disposing of their simple bouquets. They suddenly present themselves before ladies or gentlemen likely to buy—the English and Americans having their chief attention—making a curtsy and with a "Pardon, Madame" or "Monsieur," they insert their bouquet in dress or coat, and retreat. Making a short detour they present themselves with another bow for payment. To refuse the moderate sum demanded or return the bouquet under such circumstances would be out of the question.

THE FLOWER GARDEN.

NEW TUBEROUS-ROOTED BEGONIAS FOR 1879.

HAVING again grown for trial and comparison with older varieties all the new hybrids of these beautiful flowers that I could collect from the various Continental raisers during the cold, sunless, and most ungenial summer that has this year been vouchsafed to us, and having, notwithstanding the unfavourable season, succeeded in satisfactorily blooming twelve out of the sixteen single, and a similar number out of the twenty-one double-flowered varieties received (these latter, with some few exceptions, being much more delicate in constitution than their single-flowered brethren), some account of what opinion I came to as to the relative and respective merits of each variety may, I venture to hope, prove not altogether uninteresting to that large portion of your readers who take an interest in these most easily cultivated and continuous blooming plants, whose popularity with florists generally continues regularly and steadily to increase as they become better known and more widely and generally cultivated from year to year. To commence with the single-flowered varieties.

From M. Van Houtte, of Ghent, came six varieties, named respectively Madame Van Houtte, Comtesse de Flandre, François Crepin, J. Putzeys, J. B. Carnoy, and Th. Buchetet. Of the first named of these varieties the most that can be said is that it is the best of a very poor lot; it is of upright branching habit of growth, with medium-sized deep carmine flowers; on the whole of about second-rate excellence. The next on the list is a coarse growing variety, with big pointed leaves and light orange flowers, borne with considerable freedom on tall straight stems. F. Crepin is a straggling growing variety, with large, thin, poorly-formed rose-coloured flowers, sometimes partially semi-double. J. Putzeys is a small, orange-flowered, and comparatively quite worthless variety. J. B. Carnoy is a low growing variety, with peculiar, round-shaped, shining foliage, and rather thin medium-sized blossoms of a pleasing shade of deep rose colour. Th. Buchetet is a pale, washy-white, thin-flowered, and utterly worthless variety, quite unworthy of being named at all.

From M. Lemoine, of Nancy, came three varieties, two of them new—E. Legouvé and Ossian Bonnet—and one new to me—Le Paetole. Of only the first and third of these can I say anything at present, as the second named did not develop itself sufficiently to enable me to form any opinion about it. E. Legouvé is a fine variety, with large-cupped male flowers of a good clear rose colour, and of fine substance, but, unfortunately, of somewhat hard and angular habit of growth, most difficult to propagate, a fault possessed by several of the finest varieties sent out by this raiser, especially the beautiful variety named Oriflame. Le Paetole is a free blooming variety, with large flowers of a deep canary colour inside, and a reddish buff outside; unfortunately, however, the blooms are borne on long pendulous foot-stalks, which hang about over the plant, and require to be raised with the hand to see the inside of the flower. When at Ghent I saw a yellow-flowered variety named Arsene Potier, raised by M. Bordeaux, which was entirely free from this important drawback, and therefore much to be preferred, though the individual blooms were not quite so large as those of Le Paetole.

From M. Fontaine, the raiser of the splendid variety Exposition de Seeaux, perhaps the most beautiful of all single Begonias, came only one variety named Vulcain, which is a fine, vigorous, upright growing variety, with large, bold, well-formed flowers of a light orange-red colour. Perhaps this may be considered the best of this year's single varieties.

Messrs. Thibaut & Keteleer, of Seeaux, sent only one variety, named Le Géant, an exceedingly free-blooming sort of upright growing and branching habit of growth, with large flowers of clear bright carmine, unfortunately rather deficient in substance, but on the whole well worth adding to any collection of these plants.

From M. Lequin, of Clamart, came Alexandrine Lequin, an exceedingly fine variety (sent out last year, but new to me), with immense flowers of the finest substance, closely resembling in form those of another fine variety sent out at the same time by this raiser, named rosea grandiflora, and described in my notes of last year; the colour of this variety is a clear bright salmon; it should be in every collection.

Among the double-flowered varieties, those sent out by Monsieur Boucher, of Billancourt, near Paris, deserve the first place as the most vigorous and satisfactory growers of any doubles yet sent out, being of upright and freely branching habit of growth, much resembling that of the old boliviensis; they were obtained from some chance seed obtained, without any care or fertilisation, from a slightly semi-double variety, of English origin, named Dr. Moore. They are five in number, named Louis Boucher, with light orange-scarlet

flowers fully and evenly double, centre prettily fringed; Marie Boucher, deep carmine outside, centre petals of a lighter shade; Dinah Félix, light carmine, with very fully developed duplicature, perhaps the finest of this beautiful set; Duchesse de Cambaeres, fine deep carmine and large but somewhat coarse flower, tallest and strongest grower of the lot; Clovis, much the same shade as Louis Boucher, rather larger flower, but not quite so dense a duplicature, sometimes showing a whitish centre on first opening, which disappears on the complete development of the flower. Four of these fine varieties are well and accurately figured in the coloured plate of the number of the "Révue Horticole" for August 16, 1879.

From M. G. Malet, of Plessis Piquet, came two varieties named Clemence Delahaye, a delicate and low-growing variety with very beautiful medium-sized rosette-shaped blooms of a delicate rose blush colour (this variety seems better adapted for pot culture in conservatory), and Gaston Malet, a beautiful low-growing variety producing deep rose-coloured and fully double male blooms on foot-stalks well raised above the foliage.

From M. Victor Lemoine came no less than eleven varieties, but of these, from one cause or another, principally the cold and unfavourable season, only three bloomed for me; of the others I hope to give some account next year. These were Beelzebuth, a low-growing and somewhat delicate habited variety, producing flowers freely on weak pendulous foot-stalks of a light scarlet, the males of which are fully and evenly double; Rose-flora plena, a strong-growing free-blooming variety, with light rose-coloured flowers, the centres of the males of which are fully double, but not well filled up to outer or guard petals; and Viscountess Doneraile, a rather vigorous and strong-growing variety for a double, producing blooms of a pleasing shade of deep rose colour, the males of which are somewhat more than semi-double. This variety is, however, likely to be valuable as a free and continuous bloomer in the late season, and may be more double also in a more favourable season.

M. Van Houtte sent three double-flowered varieties, only two of which, however, bloomed—Comte de Flandre and Rachel, and the latter alone abundantly and well; the first named, as far as I could judge from a single flower, is of a pleasing shade of light orange, and fairly double. Rachel is fine, strong grower and free bloomer, and is interesting from being the first double yellow that has been obtained. Its colour is pale canary yellow, and the structure of its male or double flowers is quite unique and most peculiar, and unlike that of any other double variety known to me. Although very double they cannot be called a good or even double from a florist's point of view. It will, I think, be quite superseded by a fine double yellow which has been obtained by Mr. V. Lemoine, which has not yet been named. Some excellent varieties with single flowers, and a few also with double (one of which has been named Althæflora) have also been obtained after years of careful crossing and patient fertilisation by M. John Laing, of Forest Hill, who has now by far the finest and most varied collection of these plants in England. Among these is one very fine white named, I believe, Reine Blanche; and J. H. Ferrand, H. J. Laing, E. H. Woodall, and a few others, not yet sent out, are of good form and substance.

Having this autumn made a short tour on the Continent specially for the purpose of visiting the principal raisers of tuberous Begonias, and having visited the gardens of Messrs. Van Houtte at Ghent, Lemoine at Nancy, Thibaut & Keteleer at Seeaux, G. Malet at Plessis Piquet, and E. Lequin at Clamart, I came to the conclusion from what I saw there that, in the opinion of these growers, the single-flowered Begonia has reached its highest point of development, and that we must not look for much further improvement therein. Nearly all of them are now devoting their attention to the obtaining and improvement of the double-flowered kinds, and some extremely fine flowers have been obtained by nearly all of them, but especially by the two last named, which will not be sufficiently propagated to distribute till 1881. I also noted at the Seeaux garden the first single-flowered Begonia with two distinct colours, the outer half of the petals being deep nankin and the centre pure white. At Versailles I also saw a variety named Gloire de Versailles, said to reproduce itself quite true from seed, and resembling an improved form of B. Veitchii.

W. E. GUMBLETON.

Crassula alpestris.—The annexed engraving represents a pretty rock plant which has lately come into notice in this country through the instrumentality of Herr Max Leiehtlin, of Baden-Baden, who sent it to Kew a year or two ago under the name of *Sedum alpestre*. It is a neat-habited perennial, with creeping and slightly branched stems, which are of a bright reddish tint. The flowers, as may be seen, are borne in terminal clusters; they are pure white, of wax-like substance, and have orange-red-tipped stamens, altogether producing a pretty effect. Though it is a native of the Cape of Good Hope, from whence we have so many tender species of *Crassula*, it is quite hardy enough to live unprotected in this climate, as was

proved in the Kew collection during the last severe winter. It thrives well in a thoroughly drained and open position on rock-work, and continues to flower throughout the summer. Our drawing was prepared from a plant which flowered on the rock-work at the Royal Horticultural Society's Gardens at Chiswick during the present year.—W. G.

GARDEN NOTES FROM NORTH DURHAM.

THE fine autumn weather which we have had has tended greatly to mature fruit which at one time was looked upon as irretrievably lost. Of course, none of the fruit in this district attained anything like its normal size, the Hesse Pears, for instance, being very little larger than good-sized Walnuts; still they became ripe. Apples never attained much size or colour, and in flavour they were also very inferior, while, as regards keeping qualities, I am afraid they will be deficient. Peaches on walls did not ripen, and they were inferior as regards size. Perhaps nothing did so well in this neighbourhood as Victoria Plums, which were a good crop and of average quality. Small fruits were an excessive crop, but very deficient in flavour, and housekeepers who do not study the "why and the wherefore" will have much of their jam fermenting before Christmas. It was almost impossible to get the fruit gathered dry, and consequently much of it will contain a quantity of water, even after boiling. If the prejudice of cooks and housekeepers against preserving wet fruit could be removed, growers would be spared much anxiety and trouble. Fruit gathered when literally soaking with rain only requires to be boiled twenty minutes or half-an-hour longer than the regulation time, and it will then keep just as well as if it had been gathered on the hottest day imaginable, and — other things

being equal—as well flavoured; but in a season like the present, no amount of artificial treatment could make good flavoured fruit. A great amount of uneasiness was at one time felt regarding our fruit prospects next year, the prevailing opinion being that the gross growth of the present season would not be sufficiently matured. With the exception of unfavourable situations, where growth is made late in the year, fair maturation has taken place, and we have not much to fear from that source as to our fruit crop in 1880.

After the fruit crop, perhaps nothing was so disappointing as the flower garden, bedding plants of the more fashionable kinds being a marked failure. But where "carpet bedding" had been carefully managed it was decidedly superior to beds filled with flowers, where the Pelargoniums assumed alarming proportions, without ever showing any attempt to produce a single blossom. Verbenas did very badly, and Lobelias of the speciosa section sprawled all over the place. Perhaps the most satisfactory bedding plant of the year was the Calceolaria, among which that excellent old variety Aurea floribunda was the best. Judging from the specimens which I saw at local exhibitions, Asters had done remarkably well; I never saw finer shown. Speaking of the show reminds me that Dahlias were a comparative failure, although late in the year we saw some fine displays. The damp, dripping season, although it kept the Rose probably a month late, yet appeared to suit it wonderfully well, for we never saw finer Roses than those produced this year.

Amongst vegetables, although the season was sadly out of joint as regards dates, results were obtained which compared favourably with those of previous years. All the Brassica tribe grew well, and I never saw finer crops of late Cauliflowers than those of this year. I fear, however, that an excessively severe winter will be hard on the gross, succulent growth of Broccoli, Celery, and winter produce generally. A good plan is to give Broccoli a lift with a fork, which gives it a check; and Celery will need some protecting material kept in readiness for it. Perhaps early Peas were the greatest failure, generally speaking; the cold, ungenial weather in the spring retarded them so effectually that they never recovered. Mid-season crops did fairly well, and late crops were excellent. Of all Peas commend me to that excellent, early, midseason, and late sort called Ne Plus Ultra.

Indoors, early fruit crops were for a long time in the spring at a standstill for want of sunshine, but they eventually got over it, and were, to say the least, passable. Midseason Grapes were never finer, and Vines never made more growth, thus showing plainly what insatiable appetites they have for water and gross feeding. The bloom upon all late Grapes is this year thicker than is commonly the case, a fact which shows that, compared with the burning suns of last year, this has been more conducive to the production of fine fruit.

Peaches and Nectarines did well under glass, and grew to a good size. The cold weather in the early part of the year kept bees and other insects from fertilising the early blossoms; but where the trellises were shaken two or three times daily when the trees were in bloom good crops invariably followed.

On the whole, the year cannot be said to have been so unproductive as some would have us believe. Taking things generally, we may be said to have at least had average crops. We have had plenty of fruit (such as it was), good supplies of first-rate vegetables, and a

fine autumn, which has tended to make up many of the deficiencies of the year.

TYNEDALE.

A New Hardy Succulent (*Crassula alpestris*). Flowers white (natural size).

Dactylis elegantissima aurea.—This is a very pretty golden variegated Grass, having a neat compact habit of growth, and producing an excellent effect when a few good specimens of it are massed together. It would form a useful subject for dotting here and there in front of low evergreens, to the sombre hues of which its bright variegation would afford a pleasing contrast.—J. C. B.

The Best White Hardy Phlox.—Georges Sand is the finest white variety of Phlox with which I am acquainted. Its flower-trusses are very large, and the individual flowers very fine and of good substance. The habit, too, is all that can be desired. It resembles, but is in every way superior to, that fine kind White Queen, and should certainly be included in every collection of this showy family of hardy flowering plants.—J. CORNHILL.

Roses on Briers.—Whatever may be said for or against Roses on Briers, it is obvious that we cannot do without them, as the budding of choice varieties is still by far the most rapid and surest mode of increase. Many budded Roses only live a year or two, one great cause of the mortality being doubtless the transplanting of budded Briers so soon after the buds have taken. We have lately been making large plantations of Briers in beds and borders, to be budded

in their permanent flowering quarters. Thus one great cause of mortality will probably be cut off.—D. T. FISK.

NOTES OF THE WEEK.

The Heart-leaved Manettia (*M. cordifolia*).—This is one of those fine old-fashioned plants that have been displaced by new comers, though as a showy winter-flowering stove climber it would be difficult to name a more desirable one to be grown by every one. In the Palm House at Kew, twining round a pillar, it will shortly be a very attractive object. Its orange-scarlet trumpet-shaped flowers are $1\frac{1}{2}$ in. long, and are borne in long pendulous racemes from the axils of the heart-shaped leaves, and hang in graceful profusion. It is a Brazilian plant, and has long been an occupant of stoves, though but seldom seen, but, as before observed, it will well repay culture.

New Double Primulas at Fulham.—The beautiful double varieties of Chinese Primulas raised by Mr. Gilbert, of Burghley, and exhibited during the last and present seasons at South Kensington, are now in perfection in Messrs. Osborn & Sons' nurseries, where several hundred plants of them are in flower. The effect which they produce thus massed is very striking, and they cannot fail to become even more popular than the single flowering kinds, provided they prove equally amenable to culture and propagation. The largest specimens will be in full bloom in about six or eight weeks hence.

The Long-flowered Leianthus (*L. longiflorus*).—From the Gentian family we derive some of our most beautiful garden flowers, and the species under notice, which is allied to the better known and lovely kinds of *Lisianthus*, may certainly be classed among them. The bright yellow pendent flowers have each a long narrow tube and five spreading segments, with protruding stamens of the same colour. The leaves are oval and arranged in opposite pairs, and the flowers terminate the branches. It is a native of Jamaica, whence it has been received at Kew, where it is now in flower in the T range.

Orchids at the York Nurseries.—In the extensive collection of these plants in the York Nurseries, the most noteworthy at present are some splendid masses of *Lelia anceps*, of which several varieties may be traced. *L. albida*, another beautiful kind in flower, is not so generally grown as the preceding, but it is, nevertheless, a most desirable kind, as its pretty white waxy blossoms are produced so freely and last such a long while in perfection. *Cattleya maxima*, a somewhat scarce species, is likewise finely in flower, and of this, also, there seems to be several forms, varying in intensity of colour and size of blossoms.

The Narrow-Leaved Speedwell (*Veronica angustifolia*).—This elegant New Zealand shrub is a capital plant for decorative purposes during winter, and as such it is extensively grown by Messrs. Lee & Son, Hammersmith. Its leaves are much narrower than those of the Willow-leaved kind (*V. salicifolia*), and the pretty racemes of pale, mauve tinted blossoms are borne quite erect so as to be distinctly seen above the foliage. It is very easy to grow, is tolerably hardy, and thrives well in any ordinary greenhouse. In its native habitat it attains a height of from 4 ft. to 6 ft., but smaller plants of it have a more elegant appearance.

Ionopsis paniculata.—This is one of the most charming of the smaller growing Orchids, and is finely in flower in the Kew collection. It is one of those kinds with none or but very small pseudo-bulbs, and with thick leathery leaves about 6 in. long. The flower-spikes are produced from the axils of the leaves, and are from 1 ft. to $1\frac{1}{2}$ ft. long, much branched, and every branchlet bears a pretty small bluish-white flower, of which the lip is broadly heart-shaped and delicately pencilled with a purple tint. It is a native of Tropical America but is by no means a novelty, as it has been long introduced. It is strictly an epiphytal kind, and succeeds well on a suspended block. Another plant in the same house bearing the name of *I. utricularioides*, is apparently the same species.

Pitcher Plants at Chelsea.—The houses devoted to the extensive collection of *Nepenthes* now constitute one of the most interesting features in Messrs. Veitch & Sons' nursery, the majority of the plants being laden with fully developed and, for the most part, finely coloured pitchers. It is interesting to observe the varied forms, sizes, and manner of markings of the pitchers belonging to the different species and varieties. Though there are numerous novelties amongst them, such kinds as the old and well-known *N. Rafflesiana* still hold their own, though it must be admitted that most of the newer sorts have much to recommend them. Such rarities, also, as *N. Veitchi* or *lanata* may be seen with pitchers, though there are several other scarce species which have not developed any this season.

Of the newer kinds the most noteworthy are *N. Stewarti*, a fine hybrid, the result of a cross between *N. phyllanthophora* and *N. Hookeriana*. Its pitchers are very elegant and deep green in colour, spotted with crimson. *N. Kennedyana* is another novelty from North Australia, of rather dwarf habit; it has elongated pitchers that vary in colour from a reddish-crimson without to a light yellowish-green stained with red and mottled with dark crimson within. Then there is the exquisite little *N. Sedeni*, which is such a favourite with everyone, though not very new, and certainly few can excel it in the abundant production and high colour of its somewhat small pitchers.

The Cypress-like Dacrydium (*D. cupressinum*).—A small plant of this most elegant Conifer forms one of the most graceful of objects for decorative purposes. The pendulous, tail-like branchlets covered with yellowish-green scale-like leaves have a fine effect when associated with other plants. Though in its native country (New Zealand) it attains a height of 200 ft., it is of very slow growth, and remains in a miniature state for years. It is grown somewhat largely in the Fulham Nurseries in pots for decorative purposes.

Liparis longipes.—Amongst the numerous kinds of Orchids that are remarkable for the elegant appearance rather than the showiness of their flowers, this East Indian species must be regarded as one of the most attractive. The bulbs are conical and bear a pair of leathery leaves from between which proceeds a raceme a foot or more in length. It is slender and droops gracefully, and is covered throughout its entire length with hundreds of tiny singularly shaped yellow and green flowers, which emit a delicious fragrance. *L. spatulata* is another species much in the same way though not so desirable, as the flowers are produced in fewer numbers.

Cycads in Fruit.—These noble plants, beautiful as they are when covered with foliage only, are very interesting objects when in a fruiting stage. In Mr. Bull's nursery, at Chelsea, the rare *Encephalartos Vroomi*, one of the noblest of the species, is developing a huge cone, which is enveloped in a wool-like fulvous material. The new South African *E. Friderici-Guilielmi* has also for some time been in this condition, the cones of which, like the last, are covered with brownish, woolly matter.

Standard Chrysanthemums at Penrhos.—At Penrhos, Holyhead, Blush Queen of England may now be seen bearing thirty blooms, each averaging from 12 in. to 18 in. in circumference; Golden Queen of England, with thirty blooms, each averaging from 12 in. to 17 in. in circumference; also a lovely display of Mr. George Glenny and Mrs. George Rundle, with 100 blooms each; Lord Derby, Prince Alfred, Jardin des Plantes, and Bronze Jardin des Plantes are likewise bearing fine close blooms, each above the average size. There are also most of the leading varieties of Japanese kinds and Pompones, as well as late varieties, all flowering in 8-in. pots.—F. W. E.

The Century Plant (*Agave americana*).—A moderate sized specimen of this plant is now in flower in the Temperate House at Kew. The flower-stem, which rises from 10 ft. to 15 ft. in height, is quite erect, and bears a multitude of horizontal branches clothed with dense clusters of yellowish-green flowers with protruding yellow stamens. It will be for some weeks an object of interest, as the flowers do not expand simultaneously, but open in quick succession. It is interesting to observe how the huge flower stem is developed at the expense of the thick fleshy leaves; which are already much shrivelled and will eventually perish.

Senecio speciosus.—In the early part of the past summer we had occasion to allude to this plant which was then in flower in Mr. Bull's nursery at Chelsea, under the name of *S. concolor*. It is now considered to be identical with *S. speciosus*, a native of South Africa. Whatever its correct name may be, it is a very desirable plant for greenhouse decoration on account of its free-flowering habit, pretty tint of its flowers, and the remarkable length of time during which it continues in flower, for it has produced blossoms continuously from the beginning of summer until the present time.

Orchids in Flower in America.—In large collections of Orchids such as there is in Mr. Corning's garden at Tawassagunshce, Albany, N.Y., there is, at all seasons of the year, species in flower which for variety and beauty are worthy of a passing notice. There is at present in flower here such rarities as *Angraecum Chaillanum*, a very distinct and rare species; *Saccolabium bigibbum*, a very pretty, delicate species, but unfortunately the flower-spikes are too short to show the flowers off to advantage; *Cypripedium Chantini*, a kind much resembling its parent *C. insigne*, but with more white and brighter flowers, approaching in that respect *C. Maulei*; the white variety of *Lycaste Skinneri*, a superb kind, but unfortunately rather scarce; *Cattleya Dominicana alba* with eighteen flowers, forming a pleasing contrast to the rich colouring of the autumn variety, *C. labiata*. In the same collection are also *Cattleya Eldo-*

rado, a free-flowering species possessing an almost endless variety of colour, from nearly pure white to the darkest rose, with and without the purple band to the lip, and *Vanda cœrulea*, always welcome for its distinct and rare colouring. *Renanthera matutina*, noticed last June, is still in flower; this lasting quality, combined with its singular form and distinct colour, renders it at once a valuable plant; other species in flower of more or less beauty are *Cattleya marginata* (true), *Dendrobium bigibbum*, *Epidendrum pheniceum*, *Wallisi*, and *dichromum*; *Cypripedium Ashburtoniae* and *Harrisianum*; *Odontoglossum tripudians* and *erocidipterum*; *Oncidium Rogersi* (true), *Lælia autumnalis*, *anceps*, and *Perrini*; *Ceologyne Cummingi*, *Masdevallia tovensis* and *Barleana*; *Phalenopsis Lowi*, and the before mentioned *P. violacea* and *P. intermedia* *Portei*.—*F. GOLDRING.*

Holly Berries.—Christmas will not suffer for lack of these this season. Seldom has there been such a full crop, and the hedges-rows are richly coralled over with the heaviest crop of Haws that we have had for years.—*D. T. FISH.*

Cypripedium insigne and insigne Maulei.—I send you flowers of these measuring nearly 5 in. across. Most good cultivators are familiar with both varieties, but *C. insigne* is not unfrequently confounded with *C. insigne Maulei*, although the two are quite distinct; our variety of the former has been taken for the latter more than once. The white of the top lobe of *C. insigne Maulei* is as pure as the *Eucliaris amazonica*, and covers more than two-thirds of the surface, rendering the flowers very conspicuous. I look upon it as one of the very best of its class, and a first-rate showy Orchid for general culture.—*J. S. W.*

The Effect of Frost on Chrysanthemums.—About forty of these plants were placed two months ago near a wall with an aspect nearly south, in nautical language south by east. About the end of October half of them were transferred to a cool greenhouse, the remainder being moved up to the wall where their pots were half buried in dry leaves. This lot included *Eve*, *Progne*, *Sanguineum*, *Mrs. Dixon*, *Mrs. George Rundle*, *Julie Lagravère*, *Chevalier Damage*, *Lady Harding*, *Prince of Wales*, *Dr. and Mrs. Sharpe*, *General Slade*, and *Virginal*. Here they remained with no other protection than what the wall afforded till Saturday afternoon, when they were transferred to warmer quarters. *Eve* has suffered, but will probably recover sufficiently to produce flowers; *Progne* will scarcely do that, for its foliage seems hopelessly injured, and the ends of most of the shoots are bent and withered. Of the others, some are in bloom, and all look well. For the last fortnight the sun's rays, owing to the proximity of some buildings, have only reached within 4 ft. or thereabouts of the ground level, and the plants were in shadow the whole of the day. Last week a thermometer (Fahr.), in a very exposed position, registered 8°, 10°, 12°, and 13° of frost. In the open border this morning (Nov. 24) I found *White Venus* and *Chevalier Damage* severely injured by the late frosts and snow, but many of the other sorts, should there be a return of mild weather, will probably continue to bloom.—*B. S., Rutland.*

National Rose Society.—At a meeting of the executive committee of this society, held on Tuesday last, it was announced that the following special prizes would be competed for at the exhibition to be held at the Crystal Palace, on Saturday, July 3, 1880:—1, Silver challenge cup (general competition), given by Messrs. Cranston & Co., Hereford. 2, Silver cup, value ten guineas, given by Mr. John Hollingworth, Maidstone, for the best box in Class 1, seventy-two varieties (nurserymen). 3, Silver cup, value six guineas, by Mr. Thomas Hollingworth, Maidstone, for the best eighteen Teas (nurserymen). 4, Silver cup, value ten guineas, by Mr. R. N. G. Baker, Heavitree, Exeter, for the best eighteen Roses (nine Hybrid Perpetuals and nine Teas), amateurs. 5, Silver cup, value ten guineas, for the best stand of Cheshunt-raised Roses, by Messrs. Paul & Sons, Cheshunt. 6, Piece of plate, value three guineas, for the best stand in Class 14 (suburban Roses) by Mr. Edward Mawley, Hon. Sec. 7, £5 for the best seedling Rose not yet in commerce, by Mr. G. P. Hawtrey, Langley, Slough. 8, Silver-gilt medal, by the proprietors of the "Journal des Roses" for the best twenty-four Roses, three of each, one fully expanded, one half open, and one in bud.

Cardinal-flowers in Autumn.—Mr. Burbidge writes to us as follows:—"November 25th. *Lobelia ignea*, the red-folliaged variety, and the green-leaved *L. splendens*, are even yet fresh and lovely."

The Winter has come upon us earlier than usual, and it also threatens to prove one of unusual severity. A good many trees and shrubs have had their green leaves frozen on rather than ripened off, and the result will, it is to be feared, prove rather unfavourable to a rich harvest of flowers and fruit next year.

CORRESPONDENTS will greatly oblige by sending us new or rare plants for illustration.

Rockeries in Winter.—The winter months are not very cheering for those who find gardening their chief delight. A rockery may, however, become a most attractive object to all beholders even in a deep snow, provided the outline is irregular and it is replete with chinks, crannies, and small caves. These require unflinching attention so as to keep them just sufficiently open, enabling them to show to the best advantage, or the *Thymus*, *Aubrietias*, and other small plants which revel on the verge of them will interfere with the outline and soon conceal the impenetrable shadows which otherwise would be one of the chief beauties of such a construction.—*CHAS. ISHAM.*

Choretis glauca.—This Mexican bulbous plant is now in bloom in the Botanical Gardens, Birmingham. The specimen in question is producing a fine spike of pure white fragrant flowers, eleven in number. The leaves are large and glaucous, and the plant is altogether very attractive.—*J. S. S.*

COUNTRY SEATS AND GARDENS OF GREAT BRITAIN.

LONGLEAT.

LONGLEAT, one of the most beautiful houses in England, is fortunate in having its surroundings also beautiful. I have chosen the side where uninterrupted lawn reaches the house—where there are groups of great trees on a carpet of Grass. Situated in the valley there is no need for a geometrical garden here, and happily there is none to interfere with the view of the charming and airy-looking house and its pleasant surroundings, so far as this side is concerned. The house itself, too, with its abundance of light and quiet grace, what a lesson to the modern architect! who gets his effect by breaking the sky line with all sorts of useless spires and pinacles, and dreary slopes of slate with small poking windows. Here one may walk on the roof and enjoy the beautiful landscape around, and the effect is very much better than where so much is wasted to break the sky line with objects always without utility, and too frequently without beauty. However, my theme is rather away from the fine old house to the open and rolling park around, with its noble and picturesque group of Silver Firs, and, still better, those masses and groves of native hardy summer-leaving trees, so much better fitted for park scenery than the tender exotic evergreens that are now so often planted.

Neglected in many country seats, the forest department is exceedingly well done at Longleat, and is, indeed, so beautiful that it commands our first attention. The long and open drives, freely adorned with *Rhododendrons* and flowering trees, are really, in early summer, gardens of the most delightful type. There is one valley where certain huge trees of the Bird Cherry, seen in flower against masses of the Scotch and other Firs around, form a picture such as one rarely sees even in the best managed parks and woods of England. In many places the forester's duties are more closely confined to the many operations of good culture and attention to individual trees, but here it wisely extends to the nobler function of treating the woods and plantations in relation to picturesque effect, and to opening up beautiful views, an object so often neglected; and this seems to us to be an essential function of the true forester or planter. The tree, and grove, and wood—the elements which make the best parts of our country so beautiful, may, without vigorous and fasteful control, be the very cause of blotting out nine-tenths of the landscape beauty of a country seat. Many can sympathise with the love for trees, and especially old trees, which occupies itself mainly with preserving them; but it is rare that we find the still higher quality, which seeks to show them in all their beauty, adding to, and not limiting and blotting out, the landscape, and which to that end does not hesitate to sacrifice, if need be, many trees.

While there is no absence of Conifers, the common fashion of having a Pinetum near the house is not adopted here, and I think with good reason. The great popularity of Conifers during the past generation or so has led to some serious errors in landscape gardening, and to a good deal of wasted effort, for Pines are naturally trees that love the hills. They usually grow under certain well-defined conditions. While they succeed for a time in the rich little beds of soil placed under them by careful gardeners in lowland pleasure-grounds, they do not last very long when they get through that, and they as often perish in the lowland garden from cold as from drought. Now small gardens, and are obliged, every day to make the most of one spot; but in large country seats, to make the Pinetum near the house and neglect the more favourable circumstances that may be offered by the hilly slopes, or other situations around, is a great mistake. Apart from errors as to situation, the planting of Conifers near houses often leads to very great mistakes in garden design. Thus, for example, the various avenues of young Conifers at Madresfield Court very much cut up and limit the views in an important part of that fine place. So again at Woburn; an avenue of sickly Araucarias is drawn across one of the most important parts of the pleasure-ground. Apart from the question of design, there is also that of planting Conifers of doubtful hardiness as avenues. At Newstead, for instance, an avenue of Wellingtonias is by no means likely to confer much beauty or dignity on the place. No matter how wisely designed or much needed the avenue, it is almost childish to plant it with trees not of absolute proved hardiness, like our Oaks and Birches. At Longleat the Pine plantations are very well managed—as a rule quite away from the house in situations more fitted for them. Groups of all the newer Conifers are planted in well chosen sites, in some cases twenty to thirty different varieties in a group; other groups are composed of distinct kinds. Single specimens are sparingly planted, and anything like “cemetery” dotting is avoided. Bold, natural-looking groups and masses are obtained with shrubs and other flowering plants in the foreground. The age of most of the Fir woods is from seventy to eighty years. There is a beautiful drive through these Fir woods to the lake called Sheerwater, a well-formed piece of water of 26 acres, with high wooded slopes near. The screen round this lake was formerly a thick mass of common Elder; it was cut down about eleven years ago, and replanted with a great variety of ornamental trees and shrubs and many vigorous herbaceous plants. All the year round it is interesting and beautiful.

The Park contains from 700 to 800 acres, and was remodelled and planted by “Capability Brown” about the year 1754. The masses and groups of trees are well arranged and disposed throughout the beautifully undulating surface. From the high lying ground the scenery is very beautiful, especially from the spot called “Heaven’s Gate,” an uninterrupted view of the greater portion of the park, the mansion, and the distant country across the Mendip Hills and Landsdown, beyond Bath, as far as the eye can reach, being obtained. The noble avenue, which is one of the features of the park, was cut into clumps by Brown; the Marquis of Bath has had it filled up, and it is now in its original form. In the old time the park was full of straight lines and avenues; Brown transformed them from stiffness to natural landscape. The woodlands extend to upwards of 4,000 acres, of which nearly 2,000 are Oak coppice of various stages of growth, from 100 to 250 years standing, all in a healthy and thriving state, having been carefully thinned and replanted where the crop was becoming thin. The Fir and ornamental

woods contain about 1,500 acres. Numerous drives and rides intersect them; the Grass sides and slopes are planted with various flowering ornamental trees and shrubs. Groups of Pampas Grass and Tritomas are at this season effective. Many deciduous trees are annually planted in the park (Conifers are not allowed), and thus the original masses and groups are strengthened and maintained; dotting about trees is avoided, the object being to show as much broad Grass as possible.

Nothing could be more admirable than the management of the park itself and the plantations around. Larch is the only tree used as a nurse for hard-wooded trees; it does not take up so much room as the Firs, and allows a freer circulation of air. If shelter is required a group of Pine is planted on the most exposed side, taking the Austrian, Corsican, and Scotch Pines as the best and hardiest. If game covert be required, groups of Silver or Spruce Firs, nursed by Larches, answer the purpose better than indiscriminate planting. The hard-wooded trees are planted each by themselves in distinct irregular groups and groves, varying according to the nature of the soil and exposure. The old-fashioned plan of planting indiscriminately probably a dozen or a score of different sorts of trees over an acre of ground, regardless of soil or situation suited to the different trees, cannot be too strongly deprecated. In disposing of the different sorts of hardwood, masses of Beech and Sycamore are planted on poor land, and on exposed sites; next to these Wych Elm and Sweet Chestnut; and on the best land and most sheltered situations Lime, Oak, and Ash. For the sake of ornamental and landscape effect, purple Beech is introduced in clumps amongst the common Beech, the Norway and red Maple amongst the Sycamores and the Sweet Chestnuts; and groups of the white and Lombardy Poplars and American Scarlet Oak amongst the Oak and Ash. The system adopted to ensure almost certain success in planting operations is to buy two or three-year-old plants from the nurseries and grow them on in the private nursery, shifting them every two years until they are large enough to plant out. The Larches that were planted out last season averaged about 5 ft. high, with the stems nearly as stout as walking sticks, and fibrous roots like those of pot plants. The hardwoods averaged about 7 ft. high, with clean stems and good leaders, having all undergone nursery pruning, and none of them having stood longer than two years without moving. The young park trees had stout stems 3 in. or 4 in. through, with well balanced heads and roots a mass of fibres like door-mats. They are lifted one day and planted the next, the roots never being allowed to get dry.

The remarkable trees in the Pleasure Grounds are

Salisburia adiantifolia, 65 ft. high, 5 ft. 10 in. at 5 ft. up; contents 40 ft. A fine specimen.

Tulip tree, several stately specimens, the largest 98 ft. high, 11 ft. at 5 ft. up; contents 210 ft.

Swamp Cypress, 64 ft. high, 9 ft. 4 in. at 5 ft. up; contents 55 ft.

Redwood, 65 ft. high, 8 ft. at 5 ft. up; contents 75 ft.

Menzies Spruce, 59 ft. high, 3 ft. 10 in. at 5 ft. up.

Dacrydium Franklini, 31 ft. high.

Cupressus macrocarpa, 48 ft. high.

Araucaria Cunninghami, 39 ft. high.

The trees in the “Grove” at Longleat consist of Oak, Elm, Ash, Lime, Beech, Sweet Chestnut, Abele Poplar, and Silver Fir. Taken as a whole, these are probably the finest grown collection in the country. The largest specimens measure—

Oak, girth at 1 ft. up 33 ft., 5 ft. up 23 ft.; the butt contains 750 ft. of timber, the top over 200 ft. of timber.

Abele Poplar, 120 ft. high, 14 ft. 4 in. at 5 ft. up; 460 ft. of timber. 60 ft. run of stem without a branch.

Silver Fir, 133 ft. high, 15 ft. 2 in. at 5 ft. up.

Yew, 55 ft. high, 7 ft. 11 in. at 5 ft. up.

Elm, 125 ft. high, 25 ft. 2 in. at 5 ft. up; 450 ft. of timber.

Lime, 130 ft. high, 15 ft. 1 in. at 5 ft. up; 250 ft. of timber.

Yew tree on Temple Farm, adjoining the Park—height 50 ft., girth at base 33 ft. 7 in., 4 ft. up 24 ft. 9 in., smallest girth, 24 ft. 5 in. This is a sound healthy tree, circumference of branches, 168 ft.

Wherever extensive forest and ornamental planting is carried on a home nursery is almost necessary. For the vast parks of London, with their many wants, with vegetation often submitted to conditions that cause early death of the plants or trees—so behind-hand are the arrangements that there is no public nursery for the supply of these places, and the public have to get what they want in the most expen-

importance to the place, but also to the country surrounding it in making known new varieties of trees and shrubs. The nursery is on a somewhat steep slope, rather exposed, but very neatly fenced, and in perfect order. When its contents are gradually transferred to the park it will be second to none in its collections of trees, whether for profit or ornament. The young plantations cover about 650 acres, mostly planted with suitable hardwoods, according to the soil and filled up with Larch as nurses. The age of the various plantations range from one year old to fifty years. The greater portion, however, has been planted within ten or twelve years. More

Longleat. (Engraved from a sketch by Alfred Parsons.)

sive way. Although the want is much less felt in a private place, a nursery is, as has been stated, indispensable where there is the slightest attempt at the proper management of the planting department. At Longleat there is an excellent nursery not always filled with well-known plants which are to be obtained in ordinary nurseries, and perhaps grown cheaper than they could be in such a place, but well stocked with kinds by no means easy to obtain. Better still, it is an experimental nursery in the sense of containing a great many new or little known species, which are here treated as regards their hardiness and adaptability to the climate. I saw not a few kinds here for the first time. In this respect such a department intelligently arranged may not only be of great

plantations are in progress; a succession of young timber is thus ensured for the next generation.

Longleat is particularly interesting to me from being one of the first places in which the idea of the wild garden was practically carried out by the forester, Mr. Berry. With such a fine variety of surface and soil the place naturally offers numerous positions in which the plants of other countries as cold or colder than our own could be naturalised, or so planted that they would increase and take care of themselves in the woods. A forester's duties and opportunities are generally such as makes it extremely difficult for him to carry out such an idea. To know the plants even that are likely to succeed is, in itself, a species

of knowledge which every planter does not possess; however, the idea was clearly understood here, and carried out fairly well, so far as possible in the face of rabbits, which are the great destroyers of almost all flowering ground vegetation such as one would like to encourage in this way. In such a place as Longleat wild gardening cannot and should not be carried out in a small way. To get the necessary quantities of subjects necessitated a little nursery in which a sufficient number could be raised of the more vigorous perennials, bulbs, and climbers. If this new idea in gardening be carried out on the old dotting principle of the herbaeous border, its great value and its charming effects cannot be realised. To do it rightly we must group and mass as Nature does. Though we may enjoy a single flower or tuft here and there, the true way is natural fringes and masses of plants, one or two species prevailing in a given spot, so that way we may secure several important ends—different effects in different places; a variety as we walk along: better chances of meeting the wants of a plant inasmuch as dealing with a group, or mass, or carpet, we can best observe the plants, and easily see the result of our judgment in putting them in any soil or place. There-

fore, although the quantity of vigorous hardy flowers essential for making good effects in a place of this size have not yet been planted out, some very charming effects have been obtained. Views of them have been published from time to time in *THE GARDEN*, engraved from the sketches of Mr. Alfred Parsons. Among the features that Mr. Berry is working to introduce are vigorous hardy exotic creepers on old and inferior trees, Thorn, and other bushes of little value. Many are already planted, but will be some time before they show their full beauty—among them Japanese and other Honey-suckles, Virginian Creepers, Clematis, Wistarias, and

others. A part of the arboretum is more particularly devoted to this kind of decoration, and will eventually form a very wild wood and wild garden, where the Poet's Narcissus may be found among Sweet Briars, Lilacs, and many kinds of fragrant-flowering shrubs and vigorous perennials. While carrying out the scheme of wild gardening, pure and simple, that is to say, the naturalisation of foreign hardy plants, opportunity has been taken to establish beautiful native kinds where they do not happen to be present in sufficient abundance. Thus the Lily of the Valley has been brought in quantities and planted in wide-spreading colonies along the drives; and so with the Meadow Saffron and the Snowflakes and Daffodils. To group and scatter these in a natural and easy way has required considerable care, the tendency of the men being almost invariably, and in spite of themselves, almost to plant in stiff and set or too regular masses.

As to the gardens proper they have been left to the end, owing to the unusual charms of the larger garden of the woods and drives. The kitchen garden seems somewhat unfortunate as to soil and situation: it contains a Vinery of large dimensions and very well constructed, but the houses are mostly old. Here there is a peculiar and admirable culture of the Tea Rose on the northern and shady walls of

the various houses—beds raised a little above the surface—preserving the roots from the bad effects of a cold, wet soil. The results are remarkable, both as to the free and healthy appearance of the plants and the abundance of good bloom. Hardy flowers have been freely introduced once more into the flower garden, from which, as in many other places, they had long been wrongfully divorced. Here also, in the pleasure grounds, free-flowering hardy exotic plants have been allowed to spread about in a natural and beautiful manner. Of some of these engravings have been published in *THE GARDEN*, showing large spreading and perfectly natural looking groups of Summer Snowflake, Flame-flowers, and Day Lily, the last growing beside the lake as free as any water-side weed.

Longleat House was built by an Italian architect about the end of the 16th or beginning of the 17th century, and is a remarkably fine example of that transition period of architecture between the Tudor and the Renaissance, which is now called Jacobean; the large and numerous mullioned windows are Elizabethan in character, while the pillars, statues, and ornaments are in the pseudo-classical style prevalent in Italy

at that date. The effect of the building, simple in form, but with all the richness of detail which the architect brought from his native country, is that of a thoroughly English house, an interesting example of the way in which a great artist adapts his design to the purpose for which it is intended. The whole has acquired by age a fine grey colour, varied by exposure to weather and by those beautiful yellow and grey Lichens which give such a charm to any old stone-work which has escaped the ruthless hand of the restorer. The house is in the form of a square, with a central open court round which the necessary passages run, so that the windows in all the fine

Margin of Lake at Longleat.

suites of rooms command various views of the park and gardens. The front door, always left hospitably open when the family are at home, leads into a large Oak-pannelled dining-hall, with a wide fire-place, hung with antlers and strewed with the skins of strange animals, tall plumes of Pampas Grass in huge vases harmonizing well with the other decorations. There is no great collection of pictures such as many of our old mansions possess; among the most interesting works are some large animal subjects by Schuyders on the principal staircase, some portraits by Holbein or his school, and a fine full length of the present Lady Bath by G. F. Watts, R.A. In the various rooms and corridors there are some good old examples of inlaid cabinet work and of oriental porcelain, but the most valuable treasures are in the library, where are many unique books and manuscripts, an account of which was given in the "Transactions of the Somersetshire Archæological Society" a few years back. The house is willingly shown to visitors, and the public are allowed to drive or ramble through the park, and enjoy freely all its beauties, woods, and glades.

The engraving is from a sketch made during the present year by Mr. Alfred Parsons, the landscape painter.

W. R.

THE GARDEN FLORA.

PLATE CCVIII.—SOME ORNAMENTAL SPECIES
OF HIBISCUS.WITH A FIGURE OF *H. SCHIZOPETALUS*.

Drawn by CONSTANCE PIERREPONT.

The genus *Hibiscus* numbers some 150 species, and it is represented in nearly all tropical and sub-tropical regions and in some temperate countries; yet, notwithstanding its wide diffusion and the ornamental character of many of its species, few of them have retained a permanent place in gardens. With the exception, indeed, of *H. rosa sinensis* and *H. syriacus*, the genus is now hardly known in gardens, although, from first to last, nearly 100 species have been introduced and cultivated for a longer or shorter period. It is true that most of the species grow too large for small conservatories, and they are not, for the greater part, of neat and compact habit, which is doubtless the cause of their disappearance. The late Sir Joseph Paxton, writing on the members of this genus, says:—"Nothing in the large conservatory at Chatsworth, through the season in which their flowers are expanded, elicits more universal admiration than the various species of *Hibiscus*. Planted in the borders each specimen fully develops its natural character, flowering in the most profuse splendour the greater part of the summer and autumn. Some of the species grow most luxuriantly, attaining the dimensions of large trees; a greater number exhibit a less exuberant growth, forming most interesting objects; others are herbaceous, attracting attention by their tall slender stems and strikingly large gaudy flowers." The following is a selection of the most desirable species for various purposes. They vary in stature and duration from small annual herbs to large trees. The arrangement of the species is alphabetical.

H. Cameroni.—A Madagascar shrub, figured in the *Bot. Mag.*, plate 3,936, and dedicated to Mr. Cameron, at that date (1842) curator of the Birmingham Botanic Garden. The leaves are like those of the Grape Vine in shape, and the large flowers are cream or pale yellow, suffused with rose, and each petal is furnished with a bright crimson purple spot near the base. It is a tall shrub, with stout branches.

H. coccineus.—A native of the south-eastern States of North America, and hardy enough to withstand our winters, but requiring the temperature of a warm conservatory to bring it in flower perfectly. One of the handsomest of the herbaceous species, growing 4 ft. to 8 ft. high under favourable conditions. The flowers are of deep crimson, and 5 in. or more in diameter, and the elegant leaves are five-parted to the base. It was introduced in 1778, or thereabouts, and is figured in the *Bog. Mag.*, plate 360, under the name of *H. speciosus*, by which name it is better known in gardens. This is a less massive and robust species than most of the North American ones, and it is at the same time one of the showiest.

H. Colleri.—One of Mr. Bull's recent introductions from the South Sea Islands. A shrub with ovate, oblong, and coarsely toothed leaves, and double buff and yellow flowers, with blotches of crimson near the base of the petals. There is a figure of it in the "*Floral Magazine*," new series, plate 214.

H. Cooperi.—A shrub having lanceolate, oblong leaves, variegated with white and red. It was introduced some years ago by Messrs. Veitch, who received it from Australia, but its native country is somewhat uncertain. The scarlet flowers are about 6 in. in diameter; towards the base the petals are nearly white, and the centre of the flower is dark crimson. In its best condition, as represented in the "*Illustration Horticole*," plate 412, it is a very ornamental plant. Moreover, it has the advantage of being small and densely branched.

H. Denisoni.—A fine white-flowered species, imported from Australian gardens by Mr. B. S. Williams, and figured in the "*Floral Magazine*," new series, plate 232. It is a handsome species evidently allied to *H. Cooperi* from the same source; and it is probably a native of the South Sea Islands rather than Australia.

H. ferox.—A very remarkable species with large prickly leaves, not unlike those of some species of *Solanum*, and small yellow and red flowers, resembling those of a *Mahernia*. The calyx is red and the twisted petals a deep yellow. It is a native of New Granada.

H. insignis.—In Regel's "*Gartenflora*," 1876, plate 868, is a figure of a very showy *Hibiscus* bearing this name. The leaves are very much like those of the Grape Vine in shape, though smaller, and the yellow and buff flowers, with a band of crimson near the centre, are about 3 in. across. Dr. Regel states that it grows several feet high, blossoms very profusely, and deserves a place in every hothouse.

H. Jerooldianus (Paxton, *Mag. of Botany*, xiii., plate 1).—An exceedingly handsome herbaceous species, native of Brazil, and requiring a high temperature to bring it to perfection. It has digitately-divided somewhat glaucous leaves and rich, dark crimson, saucer-shaped flowers, 4 in. to 5 in. in diameter. Sir Joseph Paxton dedicated this species to the memory of the author, Douglas Jerrold. Firminger says in India it is a small, very choice, herbaceous plant, bearing in the hot season very large, splendid, carmine-crimson flowers. The stem dies down (in India) in October, and the root lies dormant until the approach of the warm weather.

H. liliiflorus.—A very handsome shrub or small tree, a native of Mauritius, Rodrigues, &c., having foliage similar to *H. syriacus*. The pink and white flowers, with a crimson centre, are about 6 in. in diameter, and the petals, instead of meeting or overlapping each other as in most of the species, are distant. There is a figure of it in the *Bot. Mag.*, plate 3144, where it is called *H. Genevi*; and plate 2891 of the same work represents a hybrid between this and *H. rosa sinensis*. This differs from the typical plant chiefly in the deeper colour of the flowers and the broader petals. The foliage of this shrub, like that of many others collected in Rodrigues by Dr. Bayley Balfour, is very heteromorphous, varying according to the age of the individual. In quite a young state some of the leaves are long and very narrow, and others are divided to the base into three very narrow lobes. This state is the *Terminalia elegantissima* of gardens. As the plant gets older the leaves become broader and less deeply lobed, and in old specimens the lobation disappears, and the leaves are ovate and acute. The gradual transition from one extreme to the other is well illustrated by a series of specimens in Kew Herbarium.

H. marmoratus.—In the size and shape of its flowers and its foliage this resembles an *Abutilon*, and was first cultivated as *Abutilon marmoratum*; but it differs from that genus in having a conspicuous involucre at the base of the calyx. The flowers are white, mottled with bright rose. It is a native of Mexico.

H. militaris.—A robust herbaceous perennial, native of the Eastern States of North America, from Pennsylvania and Carolina southward. It has handsome white flowers, veined with pink and crimson in the centre, but they are produced freely in this country in warm seasons only. It was introduced in 1804.

H. Moscheutos.—A showy herbaceous plant, 3 ft. to 5 ft. high, inhabiting the borders of marshes, particularly near the salt water, in Canada and the Eastern States of North America. It is figured in the *Bot. Mag.*, plate 882, under the name of *H. palustris*, and it is there stated that, although hardy in this country, it rarely flowers. This is probably due, as suggested by Sweet, "*British Flower Garden*," vol. iii., plate 286, to their being usually planted in too dry a situation. Pursh states that it grows in swamps and salt marshes, and flowers from August to October. There can be no doubt that this plant loves water. A curious circumstance in its history is that it was long ago naturalised along the borders of the watercourses in the Landes of France. For a long time it was regarded as really indigenous, and Thore described it under the name of *H. rosens*. Mr. Daydon Jackson, in his reprint of Gerard's "*Catalogue of Plants*," identifies "the Strange Marsh Mallow" with this species, but we think erroneously. In foliage it resembles our native Marsh Mallow, but the rose or yellow flowers are from 4 in. to 6 in. or more in diameter. It is only the yellow-flowered variety that we have seen with flowers exceeding 6 in. in diameter, and that only in a dried state from southern habitats.

H. mutabilis.—A shrub with an arboreous habit like *Lavatera arborea*, which latter, by-the-by, is a very effective hardy plant, and might well replace some tenderer subjects in what, for want of a more expressive word, is called the sub-tropical garden. *H. mutabilis*, like *H. rosa sinensis*, is commonly cultivated in the tropics, and of Asiatic origin. It has amply lobed leaves, and very large single or double flowers. Rheedé devotes five double plates to this species in his "*Hortus Malabaricus*" (1868), and in Ferrari's "*Cultura di Fiori*" (1638) there are half-a-dozen fine engravings illustrating different varieties. In the latter work it bears the name of *rosa sinensis*, from which it is at once distinguished by its large palmately-lobed leaves. Some of the double flowers figured by Rheedé are as much as 6 in. across, and resemble *Pæonies* in appearance. The specific name *mutabilis* refers to the circumstance that the flowers change colour after expansion, connected with which are some very curious stories and superstitions. When the flowers first open in the morning they are white, then they change cream-coloured and pink, and finally become of a deep rose tint. A specimen in the Kew Herbarium, collected by Dr. Sinclair in Mexico, has the following note attached to it: "From the garden of the Corregidor of Esmeraldas, where it is considered a wonder. The flowers are said to be white in the morning, red at noon, and purple at night. I saw one that was adorning a lady's hair white at break-

fast, and red in the evening." A single-flowered variety is represented in the "Botanical Register," plate 589, and a double one in Andrew's "Botanists' Repository," plate 225. The flowers of the latter are about 3 in. in diameter; one is green, another white, and a third rose. This species was first introduced into this country by Lord Portland in 1690. It requires considerable space to develop its full proportions, attaining 15 ft. to 20 ft. in height, and, although it grows in the southern part of Japan, it does not flower freely without considerable heat.

H. rosa sinensis.—This in its various forms is one of the most ornamental species of the genus, and it is a universal favourite in tropical and sub-tropical countries, being cultivated, wherever there are gardens, from Mexico to China. Two varieties were cultivated in this country, according to Philip Miller, in 1731. As is the case with many other cultivated plants, the native country of *Hibiscus rosa sinensis* is unknown, unless, as is conjectured, *H. schizopetalus* be a state of the same species. The earliest historical account of it we have seen is in Rumphius' "Herbarium Amboinense," where it is designated the Festal Flower, or Bonga Raja. The author of the book in question states that he nowhere saw it wild, but it was cultivated all over India, the Malayan Archipelago, and even in China, where he says it replaces our Roses. The natives are extremely partial to it, on account of the rich crimson colour of the flowers of the variety commonly cultivated, and they employ it in all their ceremonies, whether mirthful or mournful. Rumphius represents a double-flowered variety, and he states that he has seen one having white flowers. Firminger, in his "Gardening for India," mentions a variety with pale straw-coloured flowers, and another having double salmon-coloured flowers with a crimson centre. There is perhaps no more attractive variety than the ordinary single crimson, as represented in the Bot. Mag., t. 158, though there are some with much larger flowers. The double flowers are usually ragged and irregular. A variety called *variegatus* has the crimson petals striped with white. There is a handsome double crimson variety figured in Loddiges' "Botanical Cabinet," plate 995. It may be mentioned that the Europeans in India call this species the Chinese Shoe Plant, because they employ the flowers to polish their shoes.

H. rosa sinensis var. schizopetalus.—The *Hibiscus* represented in the accompanying illustration is a most singular and elegant plant, which Professor Oliver regards as a variety of *H. rosa sinensis*, and which he has named *schizopetalus*, in allusion to its pinnatifid petals. Dr. Kirk discovered it in Tropical Africa, and Messrs. Veitch have introduced it. They succeeded in flowering it last spring, from which plant our plate was prepared, and the Royal Horticultural Society awarded it a certificate when exhibited. The memorandum by Dr. Kirk respecting this plant is in Kew Herbarium. "The first specimen of this singular *Hibiscus* was found at Kilwa. It was then in flower, but leafless, and growing on the dry, rocky slopes of a low hill range just behind the town. The second was at the bottom of a damp mountain glen, in the Wanika hills, behind Mombasa, where it grew in perpetual shade among Bignonias, Balsams, and Ferns. Nothing could be more dissimilar than the situations of the two specimens, which were moreover separated by about 300 miles of latitude. The same plant, but of which variety I am unable to state, exists, however, at intermediate points, and I have little doubt the difference of condition indicated by the two localities, from which we have the only two known specimens is quite sufficient to account for the variation observable in the specimens now made over to Kew. I think it is still an open question whether they can be considered the true wild form and original of *Hibiscus rosa sinensis*, or an independent species. The differences are very remarkable. At the same time we must keep in mind that Africa is now coming to be acknowledged as the true centre of several Asiatic trees and plants, including Pentas and Borassus, as also the Tamarind." The differences alluded to by Dr. Kirk are chiefly in size and the degree of lobing of the petals. There is also a little diversity in the colour, which is, judging from the dried specimens, of a more rosy-purple hue in the specimen from the southernmost habitat. The largest dried flower is nearly 3½ in. in diameter. *H. schizopetalus* differs from ordinary *H. rosa sinensis*, independently of the pinnatifid petals, in the involucre at the base of the calyx being reduced to very minute teeth, or almost obsolete. In the latter the leaves of the involucre are at least half as long as the calyx. Whatever the relationship of these plants, this new *Hibiscus* is a very elegant one.

H. splendens.—An Australian shrubby species of great beauty, attaining a height of 15 ft. to 20 ft., and densely clothed with a velvety down, and more or less prickly; leaves palmately divided nearly to the base in five lobes; flowers of a uniform soft rose, and 5 in. or 6 in. or more in diameter. As Sir William Hooker remarks, the only fault of this is its size. It is a superb species, inhabiting New South Wales and Queensland, and requiring rather

a high temperature to bring it to perfection. Mr. Frazer, the discoverer and introducer of the plant, wrote of it: "This I consider the king of all the known Australian plants; I have seen it 22 ft. 6 in. high. The flowers this season measured 9 in. across, and they were of the most delicate pink and crimson, and literally covered the plant."

H. syriacus.—This hardy shrub, the *Althæa frutex* of the older botanists, is mentioned here because no selection would be complete without it, and because its merits as a late-flowering shrub are often overlooked. Our choice of late-flowering shrubs is far too limited to warrant us in neglecting so good a subject as this. True, the habit of growth is rather stiff, and the foliage rather sparse and ineffective, but this is compensated for by the fact that this shrub is the only representative of a very distinct type. The late Professor Karl Koch says, in his "Dendrologie," i., p. 485, this charming shrub is unfortunately not planted to the extent it deserves, even in favourable localities, though it is offered by nurserymen for a few pence. Even this unfavourable season the varieties of this shrub were very effective in Battersea Park. The flowers vary in colour from pure white through various shades of red and violet, and combinations of tints of the two. Nearly all of the varieties have a dark centre to the flower, but a recently introduced Continental variety, named *H. syriacus totus albus*, is wholly white, and a most profuse bloomer. Another variety, called *Céleste* by the French, is described as having flowers of a charming cerulean blue, with a crimson centre. There are also double-flowered varieties, but they are not so free as the single ones; and there are others with variegated leaves, which, however, in our opinion, are not the more ornamental for the variegation.

H. Trionum.—A dwarf, showy annual, now rarely seen in gardens. Gerard cultivated it under the name of Venice Mallow, and he remarks that "it prospereth well in my garden from yeere to yeere." The flowers are from 1½ in. to 2 in. in diameter, and of a cream or pale yellow colour, with a purple centre. Sometimes the petals are edged with purple. When annuals were more in favour this was regarded with great admiration. It is quite hardy and will often reproduce itself from seed without any trouble.

H. Wrayæ.—This is merely a variety of the beautiful South-west Australian *H. Huegeli*. It is figured and described in the Bot. Reg., 1840, plate 69. A rapid growing shrub with relatively small lobed leaves, with violet-blue flowers 3 in. to 4 in. across. Dr. Lindley states that it is of easy cultivation, growing luxuriantly in any common soil. The plant in the garden of the Horticultural Society, he continues, has been in flower for two months, and unhesitatingly predicts that it will continue to produce a succession of bloom throughout the winter and spring. Whether this hazardous prediction proved true we cannot say, but this is certainly one of the most desirable in a collection on account of the colour of its flowers.

H. grossulariæfolius, Bot. Mag., plate 4,329, belongs to the same species, differing only in being rather smaller in all its parts. It is stated in the "Botanical Magazine" that it has this character to recommend it, that in the summer, if planted against a wall, it makes a beautiful open border plant, flowering frequently during the summer months.

H. Huegeli var. quinquevulnera has lilac-mauve petals with a crimson-purple spot at the base.

H. lilacinus, Lindley, Bot. Reg., t. 2,009, is a similar plant from the same region with finely divided leaves, but it is a *Fugosia*, not a true *Hibiscus*.

W. B. HEMSLEY.

Culture.

As regards culture, the finest and those most suitable for growing in pots are the *rosa sinensis* section, but, as they come from India and the South Sea Islands, they require warmth. The plants belonging to this section are evergreen, and attain considerable height, but their natural free blooming disposition, blooming as they do when not more than a few inches high in small pots, renders them desirable subjects for cultivation, especially as they are most easily propagated from cuttings. They also bear the knife well, breaking readily when freely cut back, and in this way they may be kept for some time within a reasonably limited sized pot. The individual flowers of the single as well as the double, or, more properly speaking, semi-double, varieties are very effective; in shape they are not unlike a Carnation, but much larger. The time of flowering differs considerably according to the manner in which they are treated, but they usually bloom through the summer and autumn months. The mode of propagating is by means of cuttings, which, as I have said, strike readily with sufficient heat any time when bits of the half-ripened wood can be obtained. The most suitable shoots for rooting quickly can be got from plants that have been cut back about the close of the year, and afterwards kept in a temperature of 65° by night, and correspondingly warmer in the day. Thus treated

they break freely. When the shoots are about 4 in. long they should be taken off with a heel, and placed singly in small pots, drained, and half filled with sandy soil, the upper portion consisting of all sand. They should then be placed in a frame or under propagating glasses, where they can be kept close and moderately moist, and they will root in a few weeks. As soon as they are well furnished with roots move them into 4-in. or 6-in. pots; they will succeed in either peat or loam, but, as with most free-growing subjects of a similar character, I prefer loam, where it can be had, of a good turfy character, as in it strong-growing plants almost invariably evince a disposition to produce flowers more freely with less wood growth than when cultivated in peat. Increase the temperature of the house or pit in which they are placed as the days lengthen, giving them plenty of light with air proportionate to the temperature and state of the weather, using a little shade in the middle of the day, and syringing freely overhead in the afternoons. When the young plants have fairly started into growth pinch out the points to induce them to break back. Through the season they require nothing different from the general occupants of a warm stove. Even this first season many of them may be expected to produce flowers when, standing as they ought to be, on the front stages of the stove, they form conspicuous objects. After the blooming is over shorten them back a little, and as soon as they have broken, shift them into pots 3 in. or 4 in. larger, using soil similar to that named, to which has been added sufficient sand to keep it in a healthy, open condition. Through the autumn months, subject them to drier treatment, both as regards the atmosphere and soil; winter them in a temperature of 60° at night, or even a few degrees higher will suit them better. Their management during the ensuing spring and summer will require to be such as that recommended for the preceding year, except that no stopping should be attempted, except with the view of inducing a portion of the plants to bloom later. After they have again flowered, the shoots should be shortened back more or less, according to the size to which they are destined to be grown; but there is no state in which they are more useful than when confined to small pots. A sufficient stock should be propagated yearly, and the plants should be discarded after their second season's blooming; but, where desirable to grow them on larger when they have fairly broken, they should be turned out of the pots, as much of the surface soil should be removed as can be done without disturbing the roots in a way likely to injure the foliage, and they should be repotted in soil similar to that in which they have hitherto been grown, being guided as to size of pot by the size to which the plants are desired to be grown. They are free rooters, and will bear a shift of 8 in. or 10 in. without any danger of the soil becoming sour, and the larger the plants the greater quantity of flowers will they produce, and in this way, with additional root-room, they may be increased in size for several years; but to avoid more root-space being allowed than is convenient, they can be kept in a healthy condition with their roots somewhat restricted, making up for this by the frequent use of manure water during the growing season.

Like most plants that require a high temperature, Hibiscuses are subject to the attacks of insects; the leaves especially, if the plants are allowed to want for water, either at the root or overhead, are liable to suffer from red spider, but if the syringe be regularly used and sufficient care be taken that the water effectually reaches the under side of the foliage, this troublesome little parasite cannot get a footing. Where it happens to exist I have found the best remedy to be a weak solution of Fowler's Insecticide, in which the plants should be either dipped or syringed, so that every portion is reached by the mixture. Green fly sometimes makes its appearance on the young shoots, for which either dip the plants in Tobacco water or fumigate. Should they become affected with scale or mealy bug, sponging must be resorted to, as, except when the plants have been cut back, and are denuded of their tender foliage, the leaves will not bear any dressing strong enough to kill the insects.

T. BAINES.

Tyerman's Groundsel.—That successful amateur gardener, the Hon. and Rev. J. T. Boscawen, tells us, in a contemporary, that "unripe or even green seeds of Tyerman's Groundsel (*Senecio pulcher*) will germinate quite freely." We happen to have sown some "rather ripe" seeds of this plant three weeks ago, and can corroborate his valuable testimony. The quick germination of many seeds, notably Cereals in the ear in wet harvest times, is very suggestive, and, in the case of many other hardy flowers, the best way is to sow their seeds as soon as ripe. They thus germinate quickly, whereas, if kept long or dried they will lie dormant for months, and so much time is lost. Seeds for sale and seeds for sowing are essentially different, and we might often call to mind with advantage that Nature rarely stores her seeds up during the winter, but far oftener scatters them as soon as she has made sure of their germinating power.—B.

GARDENING FOR THE WEEK.

Flower Garden.

At the present season, the one special requirement in flower gardens and pleasure grounds is, as has been previously stated, the maintenance of neatness. Clean, firm walks, smooth turf, freshly-pointed flower-beds and shrubbery borders, produce nearly as much garden enjoyment at this dull season as flowers do in summer. At least, such is my experience, and I doubt not others have felt the same, and, such being the case, no labour should be thought too great to attain this end. Of course, where there are many deciduous trees, the fallen leaves will for the present retard the extreme neatness here alluded to, but as soon as all are down, rake out every corner, or the first windy day will blow them just where they are not wanted, and tell tales of work only half done. If the weather prove open and dry, shrub and tree moving and planting may still go on; to plant under any other conditions is simply wasted labour, for the commonest tree or shrub fails to thrive if planted whilst the soil is pasty; the reason is not far to seek—the spongioses and breathing pores of the roots are, as it were, sealed up by compression of the sodden soil about them when planting. Contemplated alterations and improvements should at once be decided on, and undertaken whilst there is time for such labour, without neglecting work which, as the season advances, requires to be done. Soil, vegetable mould, and manure should also now be got together for enriching the beds in spring, and also for potting bedding plants; these latter will require careful attention as to watering, till daylight and a drier atmosphere are on the increase.—W. W.

Auriculas.—Since I last referred to these the weather has changed two or three times. The frost, which has been of unusual severity for the time of the year, was succeeded by a few mild days, again followed by a keen east wind and sharp frosts, with a heavy fall of snow. The frames, as I write, are covered to the depth of 3 in. or 4 in. with snow; if the frost were to be intense it would be quite as well to allow the snow to remain, but as it continues to thaw it must be removed. I do not care how keen the frost may be if the leaves are dry, but frost acting upon plants through the glass causes the leaves to be covered as it were with a thick hoar frost. It involves a little trouble to throw a single mat over the glass, but it is desirable to do this rather than the plants should suffer from damp caused by the frost. During the last few days a large portion of the leaves has decayed, but we will not touch the plants until they are dry and the weather warmer, when it will be necessary to go over them to remove any portion of decay on the stems or leaves. Still continue to admit air freely when the weather is dry.

Carnations and Picotees.—Plants placed over a gentle heat are rooting freely and looking well. It is fortunate that we were able to place a portion on a hotbed; had we not done so some of them would have been practically lost for next season. Plants that have been placed out in cold frames require much the same treatment as that recommended for Auriculas. Admit air freely and see that there is no drip over any of the plants, for should a pair of valuable sorts be left under a drip, the result might be ruin to the plants in a week or two. I see the old stools that have been placed in a cool house are looking well, but the dry atmosphere is causing green fly to increase on the layers, even while they are in a temperature but little above the freezing point. For this fumigation must be resorted to.

Hollyhocks.—Where these have been recently potted, many of the leaves continue to decay, and it is quite necessary that they should be removed without delay. Such work can be done when snow is on the ground and it is difficult to get on with some operations out-of-doors. It is also a seasonable time to see to the old stakes that have been used. They may be cleaned and stored away neatly in a dry place, and any that have decayed at the base may be cut shorter, to be used next year for Dahlias, and new ones may be prepared for the Hollyhocks. In many places good stakes can be obtained in the woods from the cuttings of tall brushwood. The growths of stools of Ash or Hazel cut over when about 10 ft. or 12 ft. long answer well for stakes; but where these cannot be obtained, they may be made of 1½ in. deal cut into strips, the corners planed off, and the stakes painted green, except that part under ground, which should be painted with a mixture of equal parts boiling tar and pitch. We have had stakes last for ten years when they have been painted in that way.

Pansies in Pots.—These are never at rest during winter when the air is above the freezing point. They do not require very much attention, except to see they do not suffer from the attacks of green fly. They should now all be in their flowering pots, and as these are not well filled with roots, care must be taken not to apply any water

to the roots unless the soil is fairly dry. Give air to the frames freely, but shut them up early in the afternoon if there is any sign of frost, and cover them with mats at night.

Forcing Pinks.—Those who have not yet grown these useful plants for forcing have a treat in store. Plants of them everywhere are small this year, and they do not look very healthy, the result of the bad season: but we have potted two or three of each in one pot, and hope to have as good a display from that number as we have previously had from one plant. The best position for them now, next to a shelf in a cool greenhouse, is plunged amongst dry Coconut fibre refuse in a cold frame facing the south. The pots require moderate supplies of water, and the plants must be kept quite clean.

Polyanthuses.—It is not necessary to give these treatment at present very different from that given to Anemones. Keep the lights over them in severe weather, but give air freely whenever the weather is dry. See that none of the plants suffer from want of water at the roots, and keep green fly off the leaves by fumigating, but be careful not to over-do the fumigation, as the leaves are easily injured.—J. DOUGLAS.

Orchids.

East Indian House.—The time is now at hand when, on account of the greater portion of the plants being either actually in or approaching a state of rest, this house should be kept in the coolest and driest condition that circumstances will permit of. Where, as in very many places, there are no means of separating such portion of the stock as are making growth at this season from the greater number now dormant, it is necessary to effect a compromise by keeping up as much heat as will prevent those that are making some growth having it altogether stagnated, but yet not using so much as will keep up the growing energies of those plants that now, for more or less time, should be in no way excited. The atmosphere ought to be kept sufficiently dry without bringing it to the parching condition that sucks out the moisture from the foliage, to which we sometimes see inexperienced growers resort, under the impression that they are thus treating the plants after the manner they are subject to when growing wild in their native countries; but in which state the growth, from the full exposure to the open air, is of a stouter, less succulent character than that of plants grown under glass in artificial heat, even when treated in a way to give the growth the greatest solidity possible. It consequently becomes a mistake to submit Orchids in a cultivated state to the extreme drying process that some of them undergo in their native habitats. This over-drying process is frequently carried out with a view to induce the plants to flower, but from all that has come under my own personal experience or observation, I feel convinced that if the conditions under which the plants have been grown were not such as to impart to them the robust, gradually-matured texture in their respective parts of stems and leaves, accompanying which there is always a disposition to flower, no amount of pinching during the season of rest will do more, except with a very few species, than produce a meagre display of bloom, and which is generally at a corresponding expense in the strength of the plants. For in this matter it may be safely said that the softer the growth, with a proportionate little disposition to flower, the less the plants are calculated to bear any extreme drying process, or even as low a temperature as they will stand where the treatment has been of a character to produce short, thick, leathery leaves, and strong, stout, pseudo-bulbs. The worst effects of over-drying, especially through an absence of moisture in the atmosphere, are most apparent in *Vandas*, *Aerides*, *Saccolabiums*, and others of a like habit of growth, and I have noticed that where the atmosphere is kept too dry, unless they receive water at the roots that prevents their resting so completely as they ought, shrivelling and loss of leaf are certain to follow. The temperature for the next two months may be kept about 60° in the night, with some half-dozen degrees more in the daytime. Even with the minimum condition of moisture in the atmosphere now some slight drip from condensation on the roof is sure to take place, and falling, as it always does, from the sash bars and pulleys in particular places, it becomes necessary to look closely where these drips occur, as it frequently happens where not noticed that plants standing immediately under where condensed water falls in this way are kept so moist at the root, that the perfect state of rest required does not take place, and the roots get injured from the effects of being too wet whilst the temperature is low. The greater portion of Orchids do not need a long period of rest, or, in fact, so long as they are often subjected to when in a cultivated state; except where the object is to retard the time of flowering, I have found two months complete suspension of growth sufficient for most of the non-bulb-forming species.

Vanda teres.—This, one of the most beautiful of the genus, is rarely seen flowering well where treated like the other members of

the family. It likes an exceptionally long period of rest, keeping perfectly dry, without which its growth never wholly stops, and if this does not take place I have never been able to bloom it well. If kept for three months, or even longer, totally without water, and so as to cause its leaves to shrivel very much, no more injury to the foliage will occur than the loss of a few of the lowest and oldest leaves. The temperature of an intermediate house, such as where the majority of *Cattleyas* are grown, will suit it whilst at rest better than the warmer house.

Cœlogyne cristata.—This, one of the finest and most useful of all winter-flowering Orchids, will now be fast pushing up its bloom-stems, and will require removal to the warmest department. I frequently hear complaints that the flower-spikes after being formed do not progress; this I think in most cases is attributable to their getting wet. I have found them very impatient of moisture, and should advise from the time of their pushing up from the base of the bulbs that care be taken in giving water to the roots not to allow it to touch the spikes. Where a good stock is grown, by keeping a portion in the intermediate department for some weeks yet, a succession of flowers will be secured.

Insects.—Opportunity should be taken whilst the plants are at rest to give more attention than at other times during the year to the eradication of insects. This cleansing process, even with the greatest care, especially in the removal of scale, and the little yellow thrips that lodge in the centres of the plants, is difficult to carry out without some injury; but with the leaves, as now fully matured, and the cuticle comparatively tough, they are less likely to suffer; and I may here remark that no matter how well adapted for the purpose the houses in which the plants are grown may be, or how skilful the management in other respects, without sufficient labour at command to keep the stock thoroughly clean, it is useless to expect Orchids to ever attain the strong vigorous state, well furnished with plenty of healthy leaves, so desirable, and without which the plants never increase in size as they ought to do. Far better, particularly with plants like these, that are slow growers and costly to begin with, be content with half the quantity than cultivate larger numbers than there is means to treat as they ought to be.

Intermediate or Cattleya House.—Here the greater portion will now be at rest, particularly most of the spring-blooming *Cattleyas* and *Lælias*, and in regard to such it is not necessary to say, only to those who have had very little experience in their cultivation, that the object in view in resting these plants is to regulate their time of growing and flowering so that the growth may be made under such conditions of lengthened daylight as are essential to their well-being, for unless the flowers to be looked for are already in them in an embryo state, no extent of pinching or drying can produce bloom; but from their natural habit, with thick, fleshy, pseudo-bulbs and leaves, and the less moisture, especially to the root, that they require even when growing, they will bear keeping uninterruptedly dry for a very much longer period than the species mentioned in the warmer department; and that this has no ill effects upon them may be seen by the quantities of roots that many of the species push from the base of last year's pseudo-bulbs, and which, together with the older roots, continue growing all through the time they are kept dry. The grand old *Cattleya labiata* and *Lælia Perrini*, now in most cases with their blooming about over, need especial care, particularly the *Cattleya*, as it is very apt to be injured through its thick, fleshy flower-stems rotting, which they often do, so far as to destroy the leaves they spring from. To prevent this, it is well to cut the scape with its stem right out from the base as soon as the blooming is over, and to be careful that no water gets into it until quite dried up. Most of the *Cattleyas*, *Lælias*, *Epidendrums*, *Oncidiums*, and the like now having completed their growth, will require little root moisture for a considerable time. Here also the condition of the atmosphere as to moisture and the temperature will need to be regulated by the way in which the plants have been grown; but, as most of those at rest, as I have already intimated, will bear their roots keeping all but dry, and in this way, combined with a reduction in the temperature, all disposition to push into growth can be arrested, it is not necessary to resort to an over-dry condition of the atmosphere. A night temperature of 50° may now be kept up, and a little lower in severe weather, with a slight rise in the daytime.

Pleiones.—Where these have done flowering they should be potted in fresh material, and they should not have too much water until they have begun to root freely.

Barkerias, such as *B. Skinneri* and *B. spectabilis*, may now be kept as dry as is compatible with their not shrivelling; further than that is an absolute injury, as, from their free-flowering disposition when strong enough, they will bloom without pinching.

Brassias.—Those of the *B. caudata*, *B. guttata*, and *B. verrucosa* type will bear a long course of dry treatment at the roots, as

well as being cool, without which I have not found them to flower freely through an inclination to go off into growth. These plants are not nearly so fashionable as many species, but from their free disposition to flower when treated in accordance with their requirements, the length of time they last in bloom, the plume-like character of their spikes, and the more than usual elegance in the form of the flowers individually, they are well adapted for using in a cut state along with other flowers, though devoid of the brilliant colouring possessed by some Orchids.

Cool Orchids.—Atmospheric moisture will need to be reduced here, but not to the extent necessary for the intermediate and warmer species; neither will the plants require keeping so dry at the root, although the least heat-requiring species of *Dendrobium*, such as *D. bigibbum*, *D. japonicum*, *D. Kingianum*, *D. tetragonum*, and *D. speciosum* want to be kept with their roots dry.

Odontoglossums.—Many will now be throwing up their flowers, especially those of the crispum section; with all these, the growth of which is finished, the material the roots are placed in should be kept in a slightly moist condition; for though many growers have them wet, even in the dormant season, it is difficult to say what is gained by it beyond giving enough to keep them from shrivelling and to support the rising flower-stems; further than this any excess of moisture I look upon as not unlikely to be the cause of the spotted state the leaves are sometimes seen in. These plants will now need to be separated for some time, placing the warmer kinds, such as *O. vexillarium*, *O. Roelzi*, *O. Rossi*, *O. Phalanopsis*, *O. hastilabium*, and *O. citrosimum*, and also *Masdevallia tovarensis*, in the intermediate house.

Masdevallias.—The majority of these appear to be all but aquatic from the amount of water they need, but even in their case less is required now than at any other season, and with them, as with other plants that need much water, I should advise their being placed on some medium that will allow it to pass freely through and get away from the pots, and not to have them standing directly on shelves or boards that hold moisture, and from which the pots absorb it until the material within them is almost in a state of saturation.

Epidendrums, &c.—*E. vitellinum*, *E. erubescens*, *E. aurantiacum*, with *Lælia majalis*, the different forms of *L. albida*, and other plants of a like character now associated with the cooler *Odontoglossums*, will need to be kept dry, more or less, according to their requirements, allowing the temperature to be at about 45° at night.—T. BAINES.

Hardy Fruit.

Where the good old practise of applying surface mulchings of manure to all newly-planted trees has this season been carried out, there need be no fear that the present severity of the weather will in any way prove injurious to them. Those who have not yet so dressed fresh-planted, or recently root-pruned trees, should take the first opportunity of doing so, for such a dressing not only acts as a fertiliser, but excludes frost, and the ground being thus kept warmer, fresh root action is the sooner induced. Nor is the application of such surface manurings alone beneficial to newly-planted trees, but to all fruit trees that are in any way exhausted by over-production. As a rule, it is best to pull up and destroy old and decrepid trees, and to replace them with young ones; but, at the same time, it is well to distinguish between decrepitude and those that are only suffering from want of assistance to re-invigorate, and start them as it were, into new life. All such trees should have the old soil removed right down to the roots, and new compost, consisting of good fresh loam, bone manure, and charcoal, or wood ashes added, and afterwards a good surface dressing of rotten manure should be given them. We never fail in giving Strawberries and Raspberries such a manuring every autumn, and the results are heavy crops of fine fruit. The temperature of the ground being now about at the minimum point, and growth in fruit trees suspended, any planting still on hand would be better deferred till growth again commences in February. Meanwhile, whenever the weather is favourable push forward all such operations as pruning, training, nailing, and tying. All kinds of fruit trees, with the exception of Peaches, may now be operated on; indeed, considering the sunless character of the season, I am not certain whether it would not also be advisable to prune and retrain these to the walls at once; at least they would thus get the full benefit which walls afford as to warmth, and they certainly require it, for the wood is still very green. In any case, the trees need not be loosened from the walls with the view of retarding the flowering season, as, from present appearances, this is sure to be late. It is a very difficult matter to lay down a rule as to how, and to what extent, certain trees should be pruned; but the following may aid those who are in doubt through lack of experience: First, then, if a tree has grown extra vigorously, there is a disposition to use the knife proportionately freely; but this only

tends to aggravate the evil. The strongest growers must have the lightest pruning, and the vigour must be repressed by working down amongst the roots, and cleanly cutting off what are commonly called "tap roots," *i.e.*, roots that have developed a perpendicular form of growth without throwing out side-rootlets; when these are severed the trees become more fruitful and less productive as regards top growth. Trees that make but moderate or poor growth may, if necessary to get them into shape or form, be pruned hard, without danger of evil consequences; but, generally, such trees require but little pruning, particularly if at all subjected to summer pinching or stopping, which, after all is the most rational mode of pruning, or, rather, it is a process which renders pruning unnecessary. Apples and Pears will by this time have become inured to the temperature of the fruit-room, and therefore "sweating" will be over. The ventilators should now be always kept closed except for an hour or so at midday when the weather is fine and mild. Examine the fruit frequently, removing any that are decaying, as the fungus spores from these spread to others with great rapidity.—W. W.

Parks and Open Spaces.

The digging of shrubby borders and plantations is of the utmost importance in assisting the growth of trees and shrubs; it mellowes and sweetens the soil, breaks up the haunts of many injurious insects, and gives a neat and clean appearance to the borders. Dry weather in November and December is the most suitable time for this work, as then most of the deciduous trees and shrubs have shed their leaves. Shrubberies which have herbaceous borders surrounding them should have the Grass edges neatly cut, and the borders cleaned and mulched where necessary; all stools requiring it should also have suitable protection from frost. Where no such borders exists the shrubs may with advantage be allowed to grow over the turf, and in no way should the latter be interfered with. Prune trees and shrubs requiring it, rearrange others, or take them out altogether if needful in order to give plenty of room for the better varieties. Although it is very necessary in towns to plant liberally, care should be taken that the best trees and shrubs, especially those which are in the best positions, do not suffer from overcrowding; it is far better to secure a few fine trees and shrubs than a large number of weak ones, and by no other means can a park or open space become thoroughly and properly established. Much damage is done by neglect and carelessness in the matter of thinning out at the proper time because of the imaginary sacrifice; this is false economy however, and should be carefully avoided. Steel forks are the most useful tools for digging amongst trees and shrubs, except in very light soils, spades being much more likely to damage the roots; whatever kind of tools are used, however, care should be exercised in order to keep a sufficient distance from the stems to ensure their safety.

Various opinions exist in reference to the best season for planting, some preferring autumn, others spring. Whatever good reasons, however, there may be for choosing this or that season, one thing is certain, that planting has been very successfully carried out at any period between the end of September and the end of March: much should be left to the discretion of the individual whose duty it is to attend to the work if competent. Speaking from a lengthened experience, I would advise spring planting for wet, heavy, and retentive soils, so also should I prefer spring for street planting where the roots are so confined and but little surface allowed for evaporation. In these positions and under such unfavourable conditions I am of opinion that the sooner trees and shrubs commence their growth the more certain are they to succeed; if, on the other hand, however, they have to remain under such circumstances throughout the winter, root decay is very likely to take place to a serious extent, rendering them less vigorous to commence growth in spring. In light, porous, dry, and most good working soils, I think it is a matter of very little importance at what season planting is carried out within the above mentioned limits. In making new plantations, assuming, of course, that the sites have been properly prepared by trenching or otherwise, the best and most expeditious way to proceed is to lay out the trees first, taking a given variety and placing them, guided by the eye, "which is preferable to exact measurements," in the most natural positions. The person doing this work should be thoroughly acquainted with the various characters of each variety as to colour of foliage and flowers, height to which they may attain, habit, &c. Such trees as Planes, Poplars, Elms, Sycamore, and Birch should be placed first in position, following up with Thorns, Laburnums, flowering Peaches, and such like, which should be planted nearer to the outer edge of the plantations than the last-named. No tree should be planted at a less distance than 8 ft. from the border; if flowers are to be planted round the shrubberies the distance must be increased to from 12 ft. to 20 ft. It will be found when two or three varieties of trees or shrubs have been planted in position, the rest will be more easily arranged, their places coming more naturally by way of filling up as it were. The shrubs should be taken in

exactly the same manner as recommended for the trees, using the larger-growing varieties first. In this way one man may keep a large gang of labourers busy. The men planting should work in pairs. Where time is an object, stakes for supporting the trees may be planted with them; I do not recommend this method, however, as it is somewhat slovenly. The system of planting above described applies specially to plantations of an area of not more than an acre. Where long belts of trees and shrubs on very large areas have to be planted, the work may be done in the same manner except that, to avoid walking over the same ground too many times, it should be carried out in sections. The holes for trees and shrubs should be ample, in order to allow the roots to lie naturally, and not, as is often the case in careless planting, those roots which should be at the bottom are turned up like a birch broom to the top. Never bury trees and shrubs too deeply; the depth at which they have been growing in the nursery or elsewhere being the proper one. This is the rule, of course there are some few exceptions, where being buried somewhat deeply induces new and healthy growth; this must only be done, however, when the varieties so treated are well known to benefit by it. Trees and shrubs should be made firm by treading; but take care not to tread too near the stems. Stakes will also be necessary in the case of trees. Few things are more injurious than allowing either the one or the other to blow about loosely in the soil after planting; indeed, it is very often necessary to go over newly made plantations after high winds, to make the ground firm round any trees which may have become loosened.—C. DENNIS.

Extracts from my Diary.—December 1 to 6.

FLOWERS.—Transplanting Rose cuttings put in last January. Getting in a few more bulbs from beds outside. Taking down Stephanotis from roof of stove before scrubbing and cleaning the house. Potting herbaceous Calceolarias out of seed pans into 3-in. pots. Pruning Roses in pots for forcing. Re-arranging plant house.

FRUIT.—Planting Glou Moreceau Pears on south and east walls, and planting Cox's Pomona Apples in orchard. Untying second Peach house before pruning. Getting Vines in pots for table decoration into heat. Plunging second batch of Garibaldi Strawberries in heated frame to start them into growth. Marking ground for planting a row of Damson trees parallel with Cherries previously planted. Transplanting young Currants and Gooseberries. Pruning first quarter of Gooseberries and Apples. Pruning first house of Trebbiano Vines, and laying in shoots required for eyes in an outside border. Pruning Red Currants on north wall and pyramidal Apple trees. Watering Trebbiano border inside after pruning. Sowing first batch of Melons for early spring use of the following sorts, viz., Netted Victory of Bath and Colston Basset.

VEGETABLES.—Making up Mushroom bed outside in the form of an arch. Shifting French Beans into house prepared for them. Tying and stopping Cucumbers. Looking over Asparagus in frames, and cutting all ready for use. Potting a few more French Beans. Earthing up Potatoes growing in pots. Cutting all self-protecting Broccoli ready for use. Tying and thinning Tomatoes in Pine stove. Getting into heat a few roots of Rhubarb. Sowing a few more pots of Osborn's French Bean, and potting another batch. Potting Tomatoes out of seed pans into 3-in. pots. Covering up outside Mushroom beds with manure and mats for protection from frost and wet. Turning up ground to lie rough during the winter.—R. G., *Burghley*.

Garden Labels.—I feel rather flattered than otherwise that my remarks on labels should have evoked some discussion. What I really wished to point out was a durable label, that could be easily obliterated and used again and again. I am fully aware of the value of zinc as a material for labels; nothing that I know of can be compared with it for durability, and for the amateur, who is supposed to have order and method in all floral arrangements, nothing can, perhaps, equal it. The only fault, real or imaginary, I have to find with zinc labels is that they are too durable; and to those who have to lift, disperse, and send away or receive a large number of plants yearly I am afraid the zinc label would be useless, as the time taken to obliterate writing on zinc would be more than the label would be worth; whereas in the case of the label I have described, a touch of paint will instantly turn the old label into a new one. In public gardens a legible system of nomenclature should be adopted, and here, I think, zinc would be a failure, as a zinc label would have to be pulled out in order to be able to read it. In private gardens convenience is generally and variously studied, and a plant that interests a person is sure to have someone at hand to tell its history. I cannot see the force of the objection to a combination of wood and iron. It is a very common occurrence, and may be seen in the spade or the trundle of the garden barrow. "The combination of

wood and wire does not prevent the decay of the wood," says one correspondent. Certainly not, but the same remark will apply to the garden door on its iron hinges.—THOMAS WILLIAMS, *Ormskirk*.

THE INDOOR GARDEN.

PROMENÆA ROLLISSONI.

THE pretty little plants belonging to this genus of Orchids have, by Prof. Reichenbach, been classed as a sub-division of the larger genus *Zygopetalum*, but it is as *Promenæas* that they have long been cultivated in English gardens, and as such they will doubtless long continue to be best known. *Promenæa* is a Lindleyan genus, and for all practical purposes a good and well-founded one. Three species are somewhat commonly met with in collections, and of these the plant here represented and *P. citrina* are perhaps the most showy. *P. stapelioides* has small brown-barred flowers, and a densely

Promenæa Rollissoni.

purple-dotted labellum; therefore its flowers strike one as being extremely like those of some *Stapelia*. The blossoms of *P. citrina* (*P. xanthina* of some Continental nurseries and gardens) are smaller than those of *P. Rollissoni*, and the sepals and petals are of a soft golden-yellow colour, the column being streaked with bright red, and the lateral lobes of the lip spotted with crimson. The flowers of *P. Rollissoni* are more expanded, the sepals and petals standing clear of each other, and their colour a soft yellow, the lateral lobes of the yellow lip being barred with purple, as shown in our sketch. All the species are Brazilian, and produce their flowers during the summer or autumn months. Their culture is moderately easy. A compost of peat fibre, crocks, nodules of charcoal, and living Sphagnum Moss, seems to suit them best; and, being of tiny growth, they require but little pot room. Grown in neat little Orchid pans, such as those noticed at p. 436, and suspended near the light, they will be found to succeed satisfactorily. When growing they enjoy sunshine and an abundance of water, both at the root and in the atmosphere. We saw a fine little specimen of *P. Rollissoni* thus grown, and bearing many of its delicate flowers, in one of the little plant stoves at Glasnevin, and from a specimen supplied by Mr. F. W. Moore the present illustration was prepared. The species

belonging to this genus are *P. stapelioides*, *P. lentiginosa*, *P. xanthina*, *P. guttata*, and *P. Rollissoni*. There is another species recorded from the Organ Mountains, whence it was sent by Mr. Gardner (656). M. Descourtilz discovered it on the high range of Iha Grande, facing the sea, and with an exposure towards the rising sun. Its flowers are yellow, hence its old name *Epidendrum Jouguille*. If this species exists in cultivation, which is doubtful, it may have been confounded with its nearest ally, *P. citrina* or *P. xanthina*.

F. W. B.

JAPANESE CHRYSANTHEMUMS.

It is nearly twenty years ago since Mr. Fortune sent varieties of these Chrysanthemums over from Japan to the late Mr. Standish, from whom they speedily found their way into the hands of the late Mr. John Salter, then of the Versailles nursery, Hammersmith. The latter very speedily brought them into prominence by raising seedlings from them, the produce of seed ripened in Algiers. By sending plants there plenty of seeds were obtained, and amongst the plants thus raised were many good varieties. Mr. Fortune was unable to introduce all the varieties which were cultivated by the Japanese, but, remarkable as it may appear, Mr. Salter was able to raise from those that were introduced varieties exactly similar to those which Mr. Fortune had seen in Japan, but which he was unable to introduce. Since that time (1864) many beautiful varieties have been introduced, but those first raised by Mr. Salter are nearest to what were considered the type, viz., kinds with narrow florets, twisted, recurved, incurved, or straight. One of the most peculiar varieties was named *Tarantula*: it had a centre like a small roundish button, from which radiated a single row of perfectly straight narrow florets, of a pale yellow colour; this was the most unattractive of all, and is now probably lost, although I grew it up to two or three years ago. This variety does not seem to have been encouraged to produce seeds. *Yellow Dragon*, *Bronze Dragon*, *Red Dragon*, *Lacinatum*, and *Grandiflorum* were amongst the varieties grown by Mr. Salter in 1864, but their merits were not then fully appreciated. It was stated that they might be useful for conservatory decoration. In 1868, Dr. Masters, *Hero of Magdala*, and James Salter were distributed, followed in 1869 by *Chang*, *Aurora*, *Emperor of China*, *Giant*, *Gold Thread*, *Mandarin*, *Negro*, *The Sultan*, and *Viceroy of Egypt*. In the following year some very fine flowers were introduced by Mr. Salter, viz., *Garnet*, *Jane Salter*, *Magnum Bonum*, *Oracle*, and *Plantaganet*. Messrs. E. G. Henderson & Son also exhibited *Bismarck*, *Cry Kang*, and *Erectum superbum*. Nearly all the above flowers are grown yet: indeed, very few amongst recently introduced varieties have surpassed them.

It is very desirable that this type should be kept distinct from the other sections. *Elaine*, a very fine white flower, seems to be decidedly crossed with the large-flowered section; as is also *Peter the Great*, a more recently introduced yellow variety. One of the newest varieties possessing the charm of a brilliant crimson colour with the inner florets recurved, their exposed part being deep yellow, is named *Mons. Crousse*, and *Sarnia*, as exhibited at the Royal Aquarium, proves to be a distinct and very good flower. *Fulgore* is a very fine variety, as are also *Gloire de Toulouse* and *Fulton*, the latter a bright golden yellow. One of the most useful amongst the Japanese Chrysanthemums is *Fair Maid of Guernsey*, plants of which are grown by the hundred in some places for the production of cut flowers for market. *Elaine*, though not a true Japanese kind, is also well adapted for that purpose. Japanese Chrysanthemums are now grown very extensively, and we are not left in doubt as to their merits for exhibition purposes, or for the decoration of the greenhouse or conservatory, or as cut flowers for the drawing-room. The stands of them exhibited at the Royal Aquarium were by far the most interesting feature of that exhibition. They are not only beautiful in themselves, but they serve to relieve that sameness of aspect and regularity which the numerous stands of incurved flowers present. The Japanese kinds ought also to be exhibited in the shape of specimen plants, and it could be done in many cases without adding to the expenses. For instance, there are generally three or four classes allotted to incurved flowers, and it would be good policy to take one of these out, and give the prizes to Japanese sorts. It would not be very difficult to grow good specimens with a single stem, each furnished with two or three dozen of fine flowers. What a striking effect, for example, could be made by showing good plants of the following six sorts, viz., *Fair Maid of Guernsey*, *Yellow Dragon*, *Red Dragon*, *Sarnia*, *Monsieur Crousse*, and *Gloire de Toulouse*, grown without twisting and turning the shoots. We have seen what can be done with the Japanese kinds in the form of cut flowers, and it is only fair that we should see them grown and exhibited as specimen plants; and if once well shown in that way they will be again invited. I would urge all

raisers of seedlings to keep the Japanese group distinct; keep to the characteristics of the original varieties, and let all those of the *Peter the Great* and *Elaine* types be relegated to the intermediate sections. These two sorts may be grown as decorative flowers, but they must not be set up as belonging to the quaint Japanese type.

J. DOUGLAS.

CHRYSANTHEMUMS AT STOKE NEWINGTON.

At the annual exhibition of the Stoke Newington Chrysanthemum Society some fine examples of cultural skill were staged. The specimens exhibited were, almost without exception, of large dimensions, furnished with a dense mass of healthy foliage, and with blooms of good quality, thus affording the best of proof that a vast amount of pains-taking care must have been expended upon their culture. Whilst according to the growers that meet of praise to which their skill and patience entitle them, I cannot refrain from entering my protest against the system of training which many growers of specimen Chrysanthemums think proper to adopt. In the case of many of the plants exhibited at Stoke Newington the shoots were so closely tied down, that specimens having a spread of 2 ft. of foliage did not rise more than from Sin. to 1 ft. from the pot. Tastes vary, but I think that but few lovers of this fine autumn-flowering plant would find a realisation of their ideal in these dwarfed specimens. To my mind these over-trained plants, instead of illustrating the cultivator's art are simply examples of perverted taste and skill. The cultivator's avocation is to mend and assist Nature, not to so manipulate her productions as in a great measure to destroy their true character. The Chrysanthemum is naturally of a vigorous upright habit, and should, therefore, only receive the amount of training indispensable to the production of good blooms, and bushy, compact, or symmetrical plants. There would be some excuse for this restricted method of culture were it the only or the best manner of securing good blooms, but that such is not the case was fully proved at the exhibition in question. In the winning collection of ten plants were specimens which, although retaining all the characteristic features of the Chrysanthemum, yet left nothing to be desired either in the quality or quantity of the flowers. They served, as, indeed, all specimen plants grown for exhibition should do, to illustrate the decorative value of the plant. Conspicuous in this collection was a pyramidal but by no means formally-trained specimen of *Prince of Wales*. This plant was about 4 ft. in height, and clothed with healthy foliage and good blooms quite to the rim of the pot. Such plants as these are capable of being employed with good effect in floral decorations generally, and I would ask your readers to compare their merits with the dwarfed, cramped monstrosities above alluded to. I would also ask what purpose can be served by thus suppressing the true character of the plant. It cannot assist in the production of first-class blooms, and it certainly does not improve the general appearance of the specimen, or in any way add to its decorative value. On the contrary, I consider this dwarf flat form to be very unsuitable for conservatory decoration, or for any kind of arrangement where it might be associated with other forms of flowering or fine-foliated plants. In this view of the matter I am happy to find myself supported by many growers of great experience, and I feel certain that such examples of misplaced care, ingenuity, and patience will soon disappear from our horticultural exhibitions. Of course good shaped specimens cannot well be obtained without a certain amount of training, and in this, as in all that appertains to floriculture, the happy medium must be sought for. The great error which many growers appear to commit is that of continuing the training until too late a period, plants thus treated having much the appearance of a large dish full of foliage, with flowers dabbled into it at regular intervals. In all cases where development was less restricted the result was more pleasing, and I was gratified to see that in most of the classes the more naturally and informally trained plants carried off the premier awards. Of the standard form some marvellous examples of cultural skill were exhibited, some of the specimens of the large flowered kinds bearing quite 100 finely developed blooms. Plants of this description are very effective, and are certainly worthy of all the pains that may be bestowed upon them. Those who have large conservatories to embellish during the autumn and winter months would find the standard form of the Chrysanthemum very useful, as they may be used with good effect in situations where dwarf specimens could not well be employed. Fine as were the standard specimens at Stoke Newington, perfect in foliage and bloom, I consider that they would have presented a much more agreeable appearance had not the training been so rigidly conducted, and the individual flowers tied down so closely. I think it would be found that a more free and natural growth would not be incompatible with the production of first-class blooms. Amongst the many fine varieties exhibited the following were especially noteworthy: *Mrs. Dixon*, *Golden George Glenny*, *Mrs. Rundle*, *Hero of*

Stoke Newington, Prince of Wales, President, Jardin des Plantes, Aureum multiflorum, Empress of India, Lady Hardinge, Golden Beverage, Barbara, refulgens, Queen of England, Fanny, St. Michael, Cedo Nulli, Calliope, Golden Cedo Nulli, Antonius, Miss Nightingale, and Perle. The following Japanese kinds were very fine as cut blooms: Elaine, Bismarck, Bouquet fait, Tarantula, and James Salter. Although these Japanese forms are a wide departure from the florist's ideal, they should certainly be accorded a place in every collection. When associated with other kinds they form to them a complete and pleasing contrast, and are very effective when employed as cut bloom. Those wishing for a dozen good and distinct varieties of Chrysanthemums could not well do better than obtain the following. In forming a small collection it would be better to make some sacrifice of quality in order to ensure variety of form and colour. Some of the varieties here given are chosen on account of their distinctness, or for other good qualities which should recommend them to the small grower, who naturally desires to make the most of the space at his command. Prince of Wales, Golden G. Glenny, President, Aureum multiflorum, Empress of India, Progne, Fanny, Cedo Nulli (white), Perle, Mrs. G. Rundle, Elaine, and James Salter.

Byfleet.

JOHN CORNHILL.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Culture and Propagation of Monochætums.—Bushy little specimens of these neat habited, bright, free-flowering plants, in 4½-in. and 6-in. pots, are very serviceable for conservatory and window decoration, and, being of easy culture, they may be grown by anyone having the convenience of a frame or greenhouse. The most expeditious method of propagating them is to place a plant in gentle warmth early in the year, taking off the cuttings as soon as formed and inserting them with two pairs of leaves in silver sand. They will quickly form roots, and may then be potted off into thumb pots, to be shifted as soon as fairly established into 4½-in. and 6-in. pots. Leaf mould, peat, and light fibrous loam will be found to best fulfil their requirements in the way of soil, employing these ingredients in equal proportions, and adding thereto one-sixth of coarse silver sand. During the early spring months they should be kept in a warm, genial growing atmosphere, ventilating freely on all favourable occasions, and pinching the leading shoots in order to induce a bushy habit. By the month of June they will, if thus attended to, have formed compact, healthy, little plants, and may then be transferred to the pots in which they are to bloom. They should then be placed either in a greenhouse or frame, where they may get plenty of light and a free circulation of air around them. A little shade, will, however, be found beneficial in hot weather; and on calm warm nights, especially when accompanied by refreshing dews, the lights may be entirely drawn off; or, if grown in a greenhouse, the ventilators should be left open. By the beginning of September growth will be completed, and the plants should then be placed in the open air for two or three weeks, placing them in a somewhat sheltered and open situation where they may get the full benefit of sun and air. This exposure will have the effect of fully hardening the tissues, and will enable the flower buds to form and acquire substance. They may be wintered in an ordinary greenhouse; or, if they can be afforded a lighter position in an intermediate structure, they will come into bloom at a much earlier period.—J. CORNHILL, *Byfleet*.

Pteris serrulata magnifica.—There are many varieties of *P. serrulata* in cultivation. Your correspondent (p. 437) speaks of the "large crested variety" being a handsome decorative plant. Some are well suited for the table, others for the hall. I bought a small plant named *magnifica* from Messrs. Stansfield, of Todmorden, in 1876, which is the best variety for the latter purpose which I have seen. It now fills a 12-in. pot, and has a great profusion of fronds, varying from 3 ft. to 4 ft. long, which are bold and arching, and which keep long fresh on the plant; altogether, it is a most elegant and striking variety, and I would strongly recommend its cultivation. I am not aware that there is any larger form than this; perhaps your correspondents may be able to say.—P. NEILL FRASER, *Rockville, Murrayfield, Edinburgh*.

Salvia Bethelli.—This very beautiful *Salvia*, which was shown by Mr. Cannell at the Royal Horticultural Society's meeting at Kensington on the 18th inst., and noticed in last week's GARDEN, is quite deserving of all and much more than has been said about it. Like most of the family it is easily propagated and very easily grown. Its distinct bright pink colour and profuse-flowering habit cannot fail to make it a general favourite when it becomes better known. When well grown it continues blooming for a long time. It is named after the raiser Mr. J. Bethell, now gardener at Nonsuch Park, Cheam, Surrey.—T. BAINES.

TREES, SHRUBS, AND WOODLANDS.

AUTUMN TINTS IN TREES AND SHRUBS.

AFTER an exceptionally wet year, and a summer almost sunless, it will perhaps be worth while to note the effect they have had on the different trees and shrubs that in ordinary seasons display gay-coloured foliage in autumn. I will confine my remarks from observations taken in Longleat Park and adjacent woods, having watched the changing hues daily. The Norway Maple (*Acer platanoides*) was the first to colour, and quite out-shone all its competitors this season with brilliant and gorgeous-tinted leaves; the colours varied from yellow to glowing fiery-red. The contrast and effect, particularly in the noble and spacious avenue leading from the chief lodge to the mansion, which is planted in double rows alternately with Lime, Elm, and Norway Maple, was a grand sight to behold; the latter at their best stage of colouring seemed to be so many shining lights amongst their more sober-coloured neighbours. The park was literally lit up with them; each tree, so to speak, was like a tree on fire. Of other Maples that coloured before the fall of the leaf, the most noteworthy were *Acer colchicum rubrum* and *Acer Schvedleri*, both dying off pure yellow; the young leaves on the latter during summer are claret coloured and highly ornamental. The Tulip Tree has not appeared in its usual deep yellow-shining suit; a few trees are dying off pale yellow; but others are shedding their leaves a dull brown uninteresting colour. The Liquidambar, too, has failed to make its customary mark amongst rich autumnal-tinted trees, for it is usually beautifully coloured before dropping its leaves, often varying from purple to vermilion and other fiery colours. I am pleased to be able to note that the comparatively new purple Birch may be classed amongst, and in the first rank of gay autumn-coloured trees. A fine specimen growing here is just now clad in foliage varying from bright chestnut to vermilion. This Birch is a very free and fast grower; indeed, my experience of it is that it seems to over-grow its strength. The stem and branches become so long and slender that it can rarely withstand rough winds without suffering breakages. I intend in future when planting this particular tree to be sparing with rich soil, so as to check its over-luxuriant growth. It is a grand acquisition as a landscape tree, and can hardly be too extensively grown. Whilst speaking of Birches, allow me to draw the attention of ornamental planters and nurserymen to the upright Birch (*Betula fastigiata*); it deserves to be better known than it now is, for I think it is destined to become a most effective and useful tree, especially adapted for town and suburban parks and gardens, as well as for general landscape planting. It is not so stiff in outline as the Lombardy Poplar, being more light and airy in habit, with a strictly fastigiate growth. I believe it is of Continental origin, and, as yet, only sparsely distributed in this country. The specimens I have of it were imported from France some few years back; they are now about 12 ft. high, and I must say that I am much impressed with their distinct and characteristic appearance.

The scarlet and other Oaks, that are usually rich in autumnal tints are failures this season. Not one has come under my notice displaying a rich hue. The stately old Elms in the park are just now, Nov. 10, fine pictures in burnished golden clothing. The Beech has nearly thrown off its annual russet brown mantle, and the deciduous Cypress, *Taxodium distichum*, a shade deeper and brighter than the Beech, stands out very prominently, and is still a mass of bright warm brown coloured foliage; this tree forms a striking and pleasing contrast to all other Conifers on account of its feathery and elegant foliage. There is a weeping variety of it, but it is inferior to the type in every feature. The Wild Cherry, *Cerasus vulgaris*, must not be omitted from the list of bright, fiery tinted trees in autumn, some specimens of it here being very conspicuous and beautiful in the landscape; it is a grand pictorial tree for parks and pleasure grounds; yet how scarce it is, generally, in parks, and how seldom planted in situations which are so well suited for such a charming tree to occupy prominent sites for displaying its sheet of white blossoms in spring and brilliant autumn foliage to advantage. *Amelanchier floribunda* and *ovalis*, as usual, coloured scarlet and crimson; and *Aronia grandifolia* was also richly tinted. Some of the American Thorns were partially coloured with various tints, but not nearly so gay as in ordinary seasons.

The past ungenial, wet, sunless season seemed to have an opposite effect on different species; for instance, the Birch, although it may often be found growing and thriving almost in water, showed its decided aversion to continued rains by shedding its foliage before the summer was out, whilst, at the same time, the Oak, Elm, and Ash were quite green; the latter kept its leaves on a week or two beyond the average date of dropping. The Poplar, on the other hand, like the Birch, almost a semi-aquatic, was destitute of leaves unusually early in autumn. The Larch looked miserable all summer, and parted with its foliage very early; it has suffered severely here—

abouts, both in the young plantations and in the nursery. I also hear from other quarters that the blight is almost general throughout the country; the primary cause is, I think, the severe check in growth which it received from late spring frosts, just as it had started into active growth; and also, doubtless, the unprecedented summer of dull days, heavy rains, and cold nights—the latter were the rule, and not the exception. I do not think there was one warm genial night last summer; what is commonly called a "growing night" was conspicuous by its absence. Not only is the Larch infested with insect blight, but I fear a great percentage of them will prove worthless through the loss of their leading shoot. To nurserymen where the Larch is grown in large quantities and as a speciality the loss must be enormous. Good strong plants of Larch will probably be scarce for a season or two.

I will now offer a few remarks on autumn-tinted shrubs, amongst which the old-fashioned Sumach (*Rhus typhina*) carried off the palm for intense colours with its graceful and brilliant scarlet foliage. *Rhus Osbecki* was not much inferior, the colours being more varied. *Rhus Cotinus* was entirely deficient as regards its usual violet and red tints; indeed, it looked withered before dropping its leaves. *Euonymus europæus* shed its foliage in bright magenta colours, and laden with seed, the cases or capsules of which are hardly less attractive than the rich autumn leaves. The great advantage of this shrub over all others is that after the birds have carried off the seed the pretty seed-cases still hang gracefully on the bushes, and will remain ornamental and attractive during the greater part of the winter months. This peculiarity renders *Euonymus europæus* invaluable as an ornamental winter shrub. *Euonymus latifolius* was slightly coloured; its leaves and seed-cases are much larger than in the common variety, but the latter very soon become discoloured and drop off; it is inferior in every way to the common variety. The common Dogwood (*Cornus sanguinea*) is worthy of notice as a shrub that was well coloured this season; it died off a deep blood-red colour. Its glossy red bark, too, which is best seen to advantage after the leaves have fallen, is an attractive feature of this shrub. *Clethra alnifolia* is a late-blooming shrub that shed its leaves golden-yellow. *Virgilia lutea*, usually deep yellow in autumn, dropped its leaves a brown faded colour. *Viburnum Opulus* (the Guelder Rose) was beautifully tinted, so was *V. plicatum*. The *Viburnum* family are all good ornamental shrubs, and valuable for contrast and effect in pleasure grounds. The old variety, *V. sterilis*, snowball-flowered, is always a pleasing object, especially so when backed up by dark evergreens, its snowy-white snowball-like flowers showing up prominently. *V. macrocephalum* is a variety with immense flower-heads. *Ribes aureum* shed its leaves early, and was less brilliant in tints than it usually is in autumn; some seasons its glossy leaves exhibit a variety of lovely tints. *Cotoneaster Simmondsii* is just beginning to show up its bright red colours; when well coloured and laden with yellow fruit it forms a striking object in the ornamental woods here. The birds do not molest the seed until pressed by hunger during hard weather, which is a great recommendation amongst berry-bearing shrubs. The same remarks apply to *C. acuminata* and *C. frigida*; the fruit on them also may often be seen still hanging after most other fruit-bearing shrubs have been cleared by birds; indeed, save these berry-bearing shrubs just mentioned, there are now hardly any worth growing for the beauty of the fruit alone. Since the gun license act came into force small birds have become so numerous that as soon as the fruit is ripe it is swept off in a few days. Ten years ago I could cut any quantity of branches of the Mountain Ash covered with its beautiful fruit at Easter-tide for church decoration purposes, but now not a berry can be found a fortnight after being ripe. The *Cotoneasters* named are the only exceptions that have come under my notice. Lastly the common *Azalea* must not be forgotten as a choice autumn-tinted shrub. It has been, and still is, throughout the ornamental woods everywhere conspicuous, displaying its bright-tinted foliage of almost every hue from yellow to purple and red.

GEORGE BERRY.

The Ginkgo Tree in Fruit.—Professor Sargent (p. 430) mentions that a female tree of the Ginkgo (*Salisburia adiantifolia*), 30 ft. high, had fruited for the first time in the grounds of the Military Institute in Kentucky. Allow me to mention that some years ago, on entering the Botanic Gardens at Venice, I was greatly interested at seeing two large rotund specimens of the Ginkgo, one on each side of the gateway, and one, the female, was covered with its yellowish fruit. The leaves of both were very finely developed, those of the female being rather larger than those of the other. The odour of the outside fleshy pulp was so odious that I was obliged to wash it off (the fruit being too decomposed to preserve). The seeds resemble those of an Apricot, the margin being somewhat flattened. On sending some to Kew, Sir Wm. Hooker told me that this was the

first time that living seeds of *Salisburia* had reached this country. One of the tallest specimens of this interesting tree attained at Redleaf, in the garden of Mr. Wells, a height of 46 ft.; and one in the Botanic Garden at Pisa, sent by Messrs Loddiges to Professor Savi, was about 60 ft. in height when I saw it in 1845.—E. W. COOKE, *Glen Andred*.

WOODLAND WORK FOR DECEMBER.

THE severe weather which we have already experienced, and the present prospect of a long and sharp winter, must have convinced even the most sceptical of planters of the advantages of early preparation, unless the whole of the work of transplanting is to be deferred until spring. Every attention should now be paid to the scouring of old ditches and the cutting of new ones upon wet soils. The practice of allowing these to fill up as the plantation gets older is one which cannot be too severely censured, for as the roots of trees penetrate deeper into the soil year after year in search of food, the necessity for good drainage, and a proper attention to all water-courses and outlets increases. The unripened shoots which are now to be seen in many plantations of young Chestnut upon wet soils, teach a lesson which the forester may profit by. Upon such the spring frosts will tell heavily, and a stunted growth during the following summer will be the inevitable result.

Timber-falling may be continued without intermission, and frosty weather should be taken advantage of to remove as much of the produce as possible from the woodlands and to the sides of good roads. Where timber has to be cut up by machinery it is a great advantage to get it stacked near at hand in as clean a condition as possible. The Ash is never in better condition for working up than when felled about this season of the year. Monteath, who is no mean authority on matters of this kind, says:—"The Ash should always be felled from after the 15th of November till the last week in January, and never before nor after that time to have good timber and to do it justice."

Coppice falling will now be in full swing, but if the stools are to be left in a fitting condition to produce a good crop for the future, no cutting from the stool should take place during the prevalence of severe frosts. Wherever such is done the bark is apt to separate from the wood as the winter advances, and thus the water is admitted and the formation of adventitious buds is checked in the spring. By continuous cutting during open weather, and laying the wood in "drifts," advantage may be taken of the frost to cut up and remove from the falls.

Hop-poles should be shaved as soon as convenient after cutting, and the larger ones—here called "use poles"—should be striped or notched and covered up before spring. In Kent the allotments of underwood have realised much higher prices than were expected earlier in the season, and at many of the sales where partial credit is given the competition for lots has been brisk.

The abundance of leaves which are everywhere to be met with in plantations, rides, and in hollows where they have already drifted, will afford good opportunities for collecting and rotting to obtain leaf-mould. Too little value is generally attached to this manure by those who do not consider the large quantities of saline and mineral matters which are drawn from the subsoil by the roots of trees, and afterwards scattered upon the surface of the land by the leaves.

The cones of Larch and Scotch Fir may still be collected, and in some places the seeds of Ash and Laburnum. The rot heaps will now require to be examined, and an additional covering of earth may be placed upon them. Where small seedlings are liable to be heaved out of the ground by severe frosts, a good sprinkling of the sawdust from hard woods will be found beneficial. That obtained from Fir timber contains too much turpentine to enable it to be used with safety. Either tanners' bark or sawdust may be used for such purposes after being well rotted.

Draining, trenching, fencing, and holing for spring planting may still proceed as weather permits, and road materials may be carted during frosts. Young plantations of Birch, Ash, &c., may now be dug with advantage to the trees, and two years' transplants, which are not making satisfactory progress, may be cut off near the ground. In dry weather hedgerows may be dug and cleaned and gaps filled up by plashing from the old plants or putting in new ones. Where the soil is too light for the Hawthorn to grow into a strong fence, an admixture of Beech may be made with advantage. Upon poor or exhausted soils the Cherry Plum (*Prunus myrobalana*) will soon form a good hedge, and its formidable spines render it a good fence against cattle. It is also useful for shelter, as its leaves come out very early in the spring and remain long after the Hawthorn is bare.

A. J. BURROWS.

A remarkably long Avenue.—Dr. Finsch, in his travels in Western Siberia, just published, tells us that the great road from Nijui-Novgorod to Tiumen, in Siberia, is bordered, with a

few gaps, by an alley of Birches, which are sometimes in double rows. This, as Dr. Finsch ventures to conjecture, must be the longest avenue in the world. It was planted by order of Catherine II., and was to have been continued to Irkutsk. It was forbidden under the severest penalties—banishment to Siberia or death—to fell the smallest of these trees, a precaution without which this unique avenue would never have been finished. Many of these trees are now shattered by age, and those planted in their stead are no longer protected against damage or destruction by laws so severe as formerly. But it is pretty well known that the Russian is indifferent or hostile to trees. On the other hand, as the winter snows become heaped up in mounds around their trunks, which renders the road difficult for sledges, it is a serious question whether this avenue should not be taken away.

DESFONTAINEA SPINOSA IN IRELAND.

I WAS looking over the treasures of a fine old Irish garden near Bray Head the other day, where some South American plants are quite at home in the open air, and was delighted to find this species flowering profusely, without a sign of the severity of last winter upon its leaves or branches. It reminded one of a healthy Holly bush 6 ft. in height sprinkled with flowers of the old *Correa cardinalis*. Fuchsias were also splendidly in bloom; hardy Ferns made

Desfontainea spinosa.

every sheltered nook and corner fresh and beautiful; and *Escallonia macrantha* formed glossy green bushes 8 ft. high, and laden with pendent racemes of bright rosy flowers. Hollies were especially fine in growth, and satisfying in variety; and in the kitchen garden were the finest and healthiest Yew hedges I ever saw, and these were raised from seed by the present proprietor about fifty years ago. Planted in good, deep, rich soil, neither Yews nor Cedars are the slow-growing trees which they are commonly supposed to be. If I am not mistaken, the fine spreading Cedar at Battle Abbey, Sussex (figured in *THE GARDEN*, Vol. VIII., p. 547), was planted only sixty years ago, although, judging by its size, one might suppose that it was centuries old.

In company with the *Desfontainea* I noticed *Clerodendron Bungeanum*, fine bushes of *Eugenia apiculata*, the true Alexandrian Laurel (*Ruscus racemosus*), and a very fine large golden-cupped *Hypericum* called *H. longifolium*. In habit it closely resembled *H. oblongifolium*, but its flowers were equal in size to those of *H. calycinum*, that is, 3 in. to 4 in. in diameter, and of waxy consistence, as are also those of the oblong-leaved species. Its golden flowers, borne at the extremity of bright red stems, were indeed very lovely. The golden-leaved Chestnut succeeded admirably at the same place, every dark green leaf being powdered with gold beneath; and a cut-leaved evergreen Oak, quite distinct from the Fulham or Lucombe varieties, is an especial feature. The *Desfontainea* may not always

and everywhere be grown out-of-doors, but, as a cool greenhouse plant, it certainly is too beautiful and distinct to deserve that neglect into which of late years it has fallen. B.

THE FRUIT GARDEN.

ROOT-PRUNING.

THE differences of soil, climate, and other local conditions have such an influence upon plants, be they grown for the production of food or for purposes of decoration, that a given operation, which may be an absolute necessity in one place is often unnecessary or even mischievous in another. To this, and to the want of sufficient consideration being given to the influence which the attendant conditions above named exert over vegetable life, may, I think, be traced the wide divergence of opinion so often expressed upon the merits of any particular operation connected with cultivation that from time to time comes under discussion. Otherwise it would be scarcely possible to account for the opposite ideas so frequently found to be entertained by different individuals, who, it might be supposed, could not well disagree on matters of a mere routine character. This has often occurred to me, and in nothing more forcibly than in the extreme opposite views that appear to be entertained in reference to root-pruning. On one side are arrayed those who have practised it in different soils and situations for, may be, half a life-time, and who have so carefully noted results as to warrant them in attaching the highest value to the operation. On the other side are those who will tell you with all the confidence possible, that not only is root-pruning useless, but that it is absolutely injurious, bringing the trees so treated into an unhealthy condition from which they take years to recover. Both sides cannot possibly be right. But before venturing to suggest where the mistake lies, let me first say a word about the condition of the trees where root-pruning can with advantage be carried out, and where it is useless.

Those who advocate root-pruning, so far as I am aware, have never put forth the practice as an infallible panacea for bringing fruit trees of all kinds and under all circumstances into a bearing state, but simply urged its adoption as a means to an end with trees that are in certain conditions. The object to be kept in view in root-pruning is to check over-vigorous growth where the inclination to make wood is such that the trees fail to form fruiting spurs and bloom buds, keeping on from year to year making an extension of branches—a disposition which cannot be checked by shoot-pruning, but one which is rather aggravated than otherwise by it. This over-vigorous condition is usually to be found in the case of young trees grafted on free stocks, and that have been planted a few years in naturally rich or highly manured ground, such as in kitchen gardens, where the manure required for the vegetable crops is within reach of the roots, and thus over-excites the trees. It is in such cases as this that root-pruning can with marked advantage be performed. I may here observe that although the supply of fruit for the use of the community at large must always be most dependant upon orchard culture, and not upon the produce of private gardens, in which the mixed system of cultivation of fruit and vegetables such as that under consideration exists; still the latter is the condition in which the greatest number of people who grow fruit are placed, and where the trees are required to be grown to a size midway between those resulting from the use of such as are upon the most dwarfing stocks, and the opposite extreme of being allowed to attain their full natural size as when grown in orchards. It is here where root-pruning can be made to play a very important part by keeping the trees within the required limits as to size, and bringing them into a fruitful condition, as opposed to the alternative of shoot-pruning so severely as to make them all but barren, or else letting them grow on to a size when they would naturally come into bearing of their own accord, but which would make them altogether too large for the positions which they are required to occupy. The practise is thus beginning at the right end to curtail the organs of supply—the roots—where these are in excess proportionate to the dimensions to which the trees are wanted to grow—has common sense on its side, supported by the best results in places innumerable where it has been adopted, and the work carried out with an ordinary amount of judgment.

One or two objects can be attained by the reduction of root-power, viz., a simple check to the over-luxuriance so often present in young trees, and imparting to them the disposition to form fruit buds, which, when bearing, naturally reduce the inclination to make an excess of wood, and thus bring them into a fruitful state sooner than they otherwise would; and, in addition, where required, the size to which they grow can be regulated at will, that is, within reasonable limits. As I have already pointed out, were an attempt made to confine trees growing on free stocks to a few feet in height and diameter,

such as they would keep within when grown on stocks that have an extreme dwarfing influence, no doubt they would soon get out of health, and the fruit they bore would most likely be small in size. But extreme measures such as this are not necessary to be taken into account, as they are outside the object in view, which, as I have already attempted to show, is to secure medium-sized trees able to bear proportionately more fruit than the miniature examples resulting from the use of the Doucin or the Pommier de Paradis stocks for Apples or the Quince stock for Pears, which latter I do not like, as in very many soils the fruit is of an inferior character as compared with that produced from trees on Pear stocks; and with the Quince stock on some soils root-pruning becomes a necessity when the trees are not wanted to grow beyond a certain size.

Like most other operations connected with gardening, success depends upon the work being not only done rightly, but equally so on doing it at the right time; what I mean by doing it rightly is reducing the roots sufficiently to cause the formation of fruit buds, or to keep the trees within the required limits, or both combined, and not to go beyond this. For where such occurs it must inevitably have an injurious effect proportionate with the extent to which the excessive disrooting takes place; for instance, take an Apple that has been planted, say eight or ten years in rich soil, and which has grown so vigorously as scarcely to make any fruit buds; and if the roots of such a tree were all cut in so near to the stem as it would be quite safe to go with a tree half its size, the result would be that it would be so weakened as to take a couple of years before it made any growth at all, and though fruit-spurs and buds in plenty would most likely be formed, still these would be so weak as to be useless for a time. And I have noticed still worse results to follow from carrying out the work late on towards spring, even when the roots were not cut in more than they would have borne without injury to the trees if they had been operated upon earlier on in the winter or autumn. The extent to which it is safe to go can only be determined by the size and condition of the trees in each case, of which the operator must be the judge, and I have found it much the best with trees that have stood for any length of time without their roots being interfered with, to only go half round them on the opposite sides at once, working underneath as well to sever any roots that take a downward direction. By this means the cutting back may be carried much nearer the stem of the tree than it would bear if all were reduced at once, leaving those untouched to be dealt with at another time, soon or late, according to the effect the first operation has had, and the subsequent growth that takes place.

In the case of Apples and Pears some twelve years planted and in much too vigorous a condition to bear, I have shortened all the strong roots to within $2\frac{1}{2}$ ft. of the stem, leaving the weaker ones somewhat longer, and all the descending roots found by tunnelling under the balls at a depth of 2 ft. as well, going half round the trees on opposite sides with the best results, going round the remaining portion three years later, each succeeding three or four years going half round them again some 18 in. further away each time, and at the end of a score of years the influence in keeping them within bounds was such that they had not increased in size more than one-fifth above what they were when first the roots were cut in. They were completely studded with fruit spurs all along, bearing profusely when the bloom escaped spring frosts, the bark as clean and healthy as it could be, and when last I saw them they appeared likely to keep on for a lifetime as they did when they first came into bearing. One thing I have remarked is that exceptionally strong-growing varieties which make large trees, like Blenheim Pippin, Wellington, or Bedfordshire Foundling, do not bear their roots cutting in so as to keep them within the size required for such situations without reducing the size of the fruit, and on this account should not be planted in places of this kind. I may say that I have root-pruned with the most satisfactory results in soils as variable as they well could be for Apples and Pears to succeed, from being light and sandy to extremely heavy, but in the latter case drained so as to be sufficiently dry. Root-pruning may be carried out from the latter part of August up to mid-winter, but on no account should it be done after there is the slightest movement in the bud, except any one chooses to see what effect it has, as I have several times done with an odd tree or two, that happened to be of little account.

I have found the end of August and through September the best time for doing the work, causing a very much greater increase of bloom-buds during the ensuing year than deferring it until after the leaves had fallen, with no ill effects on the trees in any way. And as the trees to be so treated are, as a matter of course, in the first instance such as do not bear anything considerable, there need be no hesitation in carrying out the operation early. I once had the roots of a quantity of Apples, that had grown to a height of 12 ft. and as much through, and so strong that few of them had ever formed any fruit-spurs worth taking into account, cut half round in August, the remaining half being cut the year following, and the third autumn every second tree was removed to make more room,

and so little did they feel the removal, which was done with care so as to secure the newly-formed roots as much as possible, that they bore a good half-crop the summer following, the fruit, as might be expected, being somewhat under-sized.

When we hear complaints of trees being injured and refusing to grow for a time after root-pruning, it may fairly be concluded that either the roots have been too severely cut in, the operation carried out too late in the spring, or that the trees were in a condition beyond the power of root-pruning to help them. In fact I have seen trees subjected to this treatment with a view to make them bear, that instead of requiring anything to reduce their strength, were in much more need of something to put vigour into them; and yet upon such grounds the individual who so treated them condemned root-pruning as useless. I feel convinced that in such cases as I have described, where the object is to bring over-vigorous trees into a fruitful condition, and to keep them within certain limits as to size, especially when their roots have access to soil that it becomes necessary to manure heavily for other crops, there is no operation that can with such good effects be employed. I know that some people give a preference to taking up the trees altogether, but this can only be done with advantage when the trees are comparatively small, and where such are wanted it is much better in the case of Apples to plant those that are grafted on dwarfing stocks that will need little or no interference with their roots to keep them within the required size. Young standard trees in orchards, especially where the soil happens to be rich and deep, which frequently go on for years growing too strong to form fruit buds, may often with advantage be brought into bearing much sooner than they would if left to come in of their own accord, by having their roots pruned; one or two operations in their case are enough to bring them to fruiting, after which they will usually keep in a medium state of growth, as the exhausting influence of supporting crops will generally have the effect of checking over-luxuriance. I have so far confined my remarks on the subject to Apples and Pears, with which trees root-pruning is most required, and can with the most certain results be carried out, although Cherries and Plums are amenable to its influence; but in their case it is well not to reduce the roots too much. T. BAINES.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Planting Orchard Trees.—At this season, when planting is being largely carried on, it may be well to warn the inexperienced against the too common practice of planting too thickly. It is an every-day remark that two trees are put in where there is only room for one, yet fresh plantations continually come under notice in which the trees are planted much too thickly. Large, strong-growing kinds of Apples and Pears should stand at least from 25 ft. to 30 ft. apart if the soil is strong; for although many planters say they will cut out the supernumerary trees as soon as they encroach on each other, it is very doubtful whether, if they are producing anything like good crops, they are not left long enough to spoil all before any are removed. A good plan in cultivating orchards is to plant the tall standards at the fullest range they are ever likely to occupy, and to fill the intermediate spaces with dwarf spreading bush trees, as orchards thus treated are sooner remunerative than when they are all planted with standard trees.—J. GROOMER, *Linton*.

Keeping Late Grapes.—"J. S. W." tells us (p. 458) that "by giving plenty of ventilation there is no difficulty in preventing Vines from starting into growth before the month of May or even later, and that Black Hamburgs started at this season will mature their fruit by the beginning of October, so as to keep well into January or February." Now, in the first place, Vines maturing both wood and fruit early in October could not, under ordinary conditions, be kept at rest till the latter part of May or, as your correspondent states, even later; and further, as Vines not forced require some six months (more or less, according to the season) to perfect their fruit, it is evident that there would be no ripe Grapes by the time mentioned. Most of your readers, I think, will agree with me that Grapes properly "finished" before the end of September are constitutionally better, and will keep longer than those allowed to drag on into the following month.—THOS. COWPER, *Somerset Park*.

New Peaches.—Two years ago we planted several dozen young trees of the newer kinds of Peaches, with the view of testing their merits before admitting them under glass. Out of ten kinds planted, the two following varieties, Goshawk and Sea Eagle, have proved of superior excellence, although the past season has been one of the worst on record for the proper ripening of fruit, more especially such a sun-loving subject as the Peach. Goshawk is a beautiful round fruit, of large size, with a skin nearly free from down, and almost entirely suffused with crimson. It ripens in the middle of September, and is of excellent quality. Sea Eagle is a noble Peach, roundish-ovate in form, with a highly-coloured, but rather downy skin, which

will, doubtless, be improved when grown under glass. These two varieties are hardy in constitution, and set fine crops of fruit without protection last spring, when all other kinds on the outside walls failed.—J. ROBERTS, *Gummersbury*.

Gros Colmar Grape.—I was asked repeatedly the other day if the examples of this Grape, which I exhibited at South Kensington, were grown on their own root? Permit me, therefore, to say that they were not. They were grafted on a trusty friend, a fine old Black Hamburgh. The same variety "worked" on Mrs. Pearson is not satisfactory. I have a particular liking to use the Black Hamburgh for a stock. Golden Queen worked on the Black Hamburgh for pot culture last season was equally satisfactory. It is said that grafted Vines degenerate; my own experience is quite the reverse. I have a house of Vines planted twelve months back consisting of the following kinds, viz.:—Gros Colmar, Muscat, and Abercromby Seedling; the latter I like much, and the former shall be fairly tested, both grafted and on its own roots.—R. GILBERT.

Pitmaston Duchess Pear.—This is becoming a very popular Pear; it is a free grower, and produces very fine fruit, rich, and melting. One fault belonging to many of our finest Pears is that they either refuse to grow or produce such weakly wood as to be unable to perfect a crop; but this variety appears to grow well in soils of various descriptions, and I hear it highly spoken of by growers who have all the best varieties from which to select.—J. GROOM, *Linton*.

Galvanised Wire.—A correspondent in a contemporary is quite woe-begone about his trees being half ruined by being tied to galvanised wires. He is told to tie a twist of matting round the wire as a preventive, but time being money, I say paint the wires in question with two good coats of paint, and the difficulty will vanish at once. This is not theory, but practice.—R. GILBERT.

THE KITCHEN GARDEN.

FORCING VEGETABLES.

Asparagus.—This is perhaps the most important vegetable that is forced during the winter; and there are two ways of forcing it, each having its advantages and disadvantages. The old way, still commonly practised, is to force the plants in the beds where they grow by means of a frame and hot linings. The advantages of this plan are that one has not the trouble of lifting the roots, and, not having been disturbed, the shoots are stronger and finer; and, lastly, the plants are not afterwards lost, as is usually the case with roots lifted to force, because the roots are left in the ground, and, by an alternate system of forcing the beds, they recover again and are soon as good as ever. The objection to the plan of forcing the plants in the open ground is its cumbersomeness; but the answer to this is that the plan is not necessarily so cumbersome as some make it. The usual practice is to grow the plants in beds 4 ft. or 5 ft. wide, with 2 ft. alleys between, which are dug out at the forcing season to the depth of 2 ft. or so, and filled in with fermenting materials, the top of the bed being covered by a frame of some kind. So much labour is not necessary, however, unless it be in the autumn, when the plants start rather reluctantly. The Asparagus does not need a high temperature to make it push quickly, nor is it desirable to subject the roots to much heat, otherwise the tops will be poor and weak and ill-flavoured. It will generally be found sufficient in forcing in the open ground to cover the bed, or part of it, with a shallow frame facing the south if possible, and covered with glass sashes, and lined round the sides with a good thickness—say 2 ft. or 3 ft.—of litter and leaves in even quantities, and also combed over above till the stems appear, when light and sunshine may be admitted both to warm the soil and green the tops a little. During the spring months Asparagus may be easily forced in this way. The tops are a little longer in moving than in the forcing house; but this may be easily provided against by beginning to force a little sooner. It is surprising how very little protection and heat excite Asparagus, Rhubarb, and Seakale into growth after the turn of the year. Seakale begins to push early in the season if the crowns are only protected by a spadeful of litter, and so does Rhubarb. We have gathered stalks of the Early Linnæus in February by putting a barrowful or less of long litter over each stool at the end of October, and Asparagus pushes just about as readily. In forcing the latter in the forcing house by means of hot-pipes or a hotbed, the great point is to get the plants up from the ground with as many good roots as possible, and without mutilation. They should also be taken up in open mild weather, and in prospect of frost two or three batches may be lifted at the same time, and protected by a covering of soil in some cold shed till needed. The roots may be packed pretty closely together in the forcing bed, but carefully, and filled in between and covered

over a few inches with any light loose soil at hand. It is not the culture in the forcing pit that produces firm heads so much as the previous culture in the beds, and care in lifting; but, at the same time, good stools will throw off very weak heads if they are pushed on in a too high temperature. A gentle hotbed of leaves is all that is required, and that only before the new year; afterwards the roots will force freely enough in a temperature of from 55° to 60°, a figure which the bottom heat should not exceed at any time. Asparagus is usually forced in shallow frames set on a 2 ft. or 3 ft. deep bed of leaves; but it may also be forced quite well under a greenhouse stage, in a Peach-house, in a Vinery not long started, or in any structure where the above temperature can be maintained. All the attention which the roots will need will be occasional watering with tepid water.

Seakale.—This vegetable will grow slowly if it be subjected to a temperature slightly above 42°; but it is better to force it in a temperature from 8° to 13° higher. A too high temperature produces long, soft, and woolly stalks which do not cook well; while a low temperature produces stalks that are tough and stringy. About 55° will suit it well. Seakale may be forced early in the open ground by placing an inverted flower pot over each head, and filling in between the pots with stable litter till the pots are quit covered. This generates sufficient heat to excite the plants into growth at any season of the year; and, as the warm days of March and April come on, little more is required than the pots to keep the plants dark, and a slight sprinkling of litter or leaves. By this plan anyone may have a steady supply of Seakale from his garden year after year with little trouble. When a large quantity is required, however, we prefer to force Seakale in the forcing house—in a Mushroom house or underground cellar, for example. The roots, unlike Asparagus, can be lifted without danger, and quickly, and forced with ease and convenience; and they may afterwards be kept for forming fresh plantations in the open ground. The first heads are of course always the strongest and best, and should be cut off close to the crown; but the roots should not be removed, as they will produce another crop of more slender tops, to be sure, but still of a useful sort; sometimes, even excellent, just according to the strength of the roots. We always take two cuttings from our Seakale, and find both useful in the kitchen; and what is to spare we can always sell.

Rhubarb.—Rhubarb roots, if lifted without much injury, and placed in a tolerably warm cellar, or a Mushroom house, or any other dark place where the temperature ranges from 50° to 60°, will soon push and afford a plentiful supply. It is also forced very easily in the open ground. The best plan of forcing the plants where they grow I ever saw was in a garden in the north, where the plants were grown in small plots of sixes, and much closer together than usual. When forced a few stakes were driven in round the plot, and against and between these a wall of fermenting material was packed to a height of about 3 ft. Some Scarlet Runner sticks were then laid across the top, which was covered with mats and a little straw, and that was all. The stalks had room to grow, were plentiful, long, and thick. When it was thought one plot had been forced enough, the materials were moved on to the next plot, and so on; but the same plots were not forced every year. As spring advances a good covering of long litter over the crowns of the plants is sufficient to bring them in a month or six weeks earlier than they would come in the ordinary course of culture.

Chicory.—This is one of the easiest of subjects to force. Its vitality is hardly ever dormant, and it consequently does not want a rest previous to forcing, like the Asparagus or Seakale. A few roots lifted and divested of their green leaves, but without injuring the growing crown, if potted closely together in any ordinary soil or planted in a bed or in a box, or anything convenient, and placed in a cellar where the temperature ranges about 50° to 55°, will produce a good supply of salad for a while; and it is an easy matter to introduce successive supplies of roots as often as needful. I do not know any salad that people having small gardens might grow and force more successfully, and with so little trouble. Wherever Lettuces and Endive are scarce during the winter, fall back on the Chicory; it is equally as good as Lettuce when well blanched, and quite as wholesome. If Mustard and Cress can be grown along with it, all the better. These three make no mean winter salad, and all may be had in quantity by anyone for the trouble of growing them.

Lettuces.—These are usually grown in shallow frames, or under hand-lights or cloches. We prefer shallow frames in this country. Our plants have been planted sometime; the Hardy Hammersmith is the variety used, and the seed is sown in the frame in September or October, in rows about 4 in. asunder, and, as the young plants are always good and tender, the thinnings are used, if necessary, for salad, as long as they last, the main crop plants being left 7 in. apart to heart. They generally last us right through the winter, continuing to grow all the time with scarcely any artificial heat. Let-

tuces will not bear forcing; they will grow, but will not heart, if excited by such means. The Hammersmith grows at a very low temperature. Another way of forcing the Lettuce is to sow the seed in boxes, like Mustard and Cress, and cut over the young seedlings in the same way when about 2 in. high. Such Lettuces are quite tender and good, and I can recommend the plan.

Radishes.—These force easily during the winter. The seed should be sown in a shallow frame, or in boxes or pans, in light soil, and the plants must be thinned out before they crowd each other in the least, otherwise they will not tuber. Two inches between the plants and 4 in. between the rows will be sufficient. The Early Frame is the best sort for forcing.

Carrots.—These succeed under exactly the same conditions as Radishes. The Early French Horn is the best for forcing. A crop of Radishes may be taken off from between the rows before they are munched in the way of the Carrots. A temperature of about 55° should be afforded during their growth, and a rather higher figure on sunny days.

Cheese Herbs.—These include Mustard, Cress, young Onions, and Tarragon. The first two require just a word, for, simple as the matter appears to be, plenty fail to maintain a constant supply of Mustard and Cress during the winter months; and the reason is that they give both too much heat. Sow the seed in shallow boxes in light soil, and not so thickly as to let the seeds touch each other; cover very slightly or scarcely at all with fine soil, and lay a board or sheet of brown paper over the box; place it in a temperature of 60° or 65° and water sparingly. In a day or two the seed will vegetate, when the paper should be removed, and the plants exposed to the light. In another day they will be greened and fit to cut, and if the box be removed to a cool dry house, where 45° is maintained, it will keep for a week in usable condition.

Onions are used when just coming through the soil, and before they pass out of the seed stage and get their tops erect; after that they are too old for the purpose. A boxful should be sown about once a fortnight, and treated like Mustard and Cress.

Tarragon.—Green Tarragon can generally be picked out-of-doors till December, but after that it must be forced in pots. The plants to be forced early should be cut down in October, and be lifted carefully, and potted in light, rich soil, and forced in a gentle temperature, such as that of an early Peach house. The plants will force two years in the same pots. In fact, it is the best plan to hold over a few of the old pots for forcing early. It saves the outdoor plantations of Tarragon, which is the most precarious subject belonging to the herb border. J. S. W.

MESSRS. CARTER & CO.'S ROOT SHOW.

This took place at the Agricultural Hall, Islington, on the 21st inst., and, notwithstanding the late sunless and otherwise unfavourable season, the show was a large one, and the exhibits were, on the whole, of average quality. The classes for the various prizes offered were well filled, and in most cases there was a keen competition. The classes which were interesting to the gardener more directly were the collections of the various vegetables, including Potatoes, though these formed but a comparatively small item in the exhibition. The best collection of twelve kinds of vegetables was exhibited by Mr. Iggulden, gardener, Orsett Hall, Romford. It consisted of excellent dishes of Reading Onion, Musselburgh Leek, James's Intermediate Carrot, Snowball Turnip, Imperial Brussels Sprouts, Carter's Incomparable Celery, International Kidney Potato, Trophy Tomato, &c. The next best collection, which was also remarkably good, contained some fine examples of excellent culture. There were several other exhibitors in this class, the majority of whom showed good collections. The class for eight dishes of Potatoes brought out several competitors. The first prize was taken by Mr. C. W. Howard. The best varieties shown were Schoolmaster, Grampian, International Kidney, Brownell's Superior, and Snowflake. The second and third collections, too, were very good. The best dish of Improved Magnum Bonum Kidney was shown by Mr. Creed, and the second prize was taken by Mr. Iggulden. Excellent dishes of Onions were shown, the first prize for them being awarded to Mr. E. Thorn. The red and white and yellow kinds of Carrots were well represented, especially the red kinds, the first prize for which was taken by Mr. G. Cole with well-grown roots. The Cabbages shown were Drumhead, very large, the heaviest being from Mr. Greatorex, and the next heaviest from the gardens of the South Metropolitan District Schools. The roots grown on farms were for the most part excellent. Some, such as Carter's Mammoth Red Mangold, weighed nearly 40 lb. The exhibition of roots alone, which extended throughout the entire gallery of the hall, afforded an interesting sight for those interested in such matters.

ANSWERS TO CORRESPONDENTS.

Boronia megastigma.—"M. M." asks (p. 474) how to flower this plant in spring, but does not say what time in spring. All the family are spring-bloomers but this sort does not appear to come in so early as some of them. I have had *B. pinnata*, the finest of all the species, with open flowers upon it from November up to the June following and at its best in May, but during the whole winter and spring it was in a north house with the temperature kept as low as was safe consistent with excluding frost; yet this is lower than any of the family really like, and unless the plants have been exposed for a few weeks in the open air during the latter part of summer, they will be subject to mildew when kept so cool. A night temperature of 40° or 42° will answer for all the kinds, with a slight rise in the daytime with sun-heat; but they, and all plants from the same region, should never be under the influence of fire-heat, except so far as to keep up the temperature above named, as the excess of warmth is sure to induce premature growth before the length of daylight and the amount of air which they can have are such as to give solidity to the growth made; an accompanying consequence would also be that the flowering would be over much earlier than it ought. *B. pinnata*, *B. serrulata*, *B. Drummondii*, *B. elatior*, and *B. megastigma* are all desirable, long-flowering plants that will succeed with similar treatment, but, if any, *B. serrulata* likes a little more warmth than the others in winter.—T. BAINES.

Cloches.—In reply to Mrs. Ricardo's enquiries respecting the use of cloche^s (p. 474), I can assure her that there is nothing in their way equal to these French glass bells, not only for growing Lettuces, Endive, and the like for winter, but also for covering choice little plants of other kinds in winter that need protection. The advantage belonging to their use over that of garden frames for winter Lettuces especially is derivable from the full volume of unobstructed light which they afford, and which any one who has seen the plants growing under them cannot fail to have noticed, as compared with that received by those in wooden frames or brick pits, with their dark sides, only admitting light from above, and which always have the effect of causing whatever is grown in them when of a soft character to be more or less drawn, added to the greater distance which the plants in frames are from the glass overhead, and which tends to a weaker condition of growth. I have used cloches for many purposes, but particularly for Lettuces, Endive, and Radishes in winter and early spring, usually in two rows together, with walking space between them and the next two rows, and room between each set of plants for the glasses to stand when taken off if need be; but for such plants as the above, from the full light which they give, it is seldom necessary to take them off altogether in the winter season. The covering which I used in severe frost was Fern or Gorse laid on in thickness proportionate to the severity of the weather, but from the sturdy character of the plants grown under these glasses, as compared with similar plants in frames, I always found the former able to bear much more frost. It is necessary to keep the covering material on so as to prevent the sun from coming on the glass when the plants are frozen, or they are liable to be so far injured as to be useless.—T. BAINES.

Bones as Manure.—*B.*—Crushed bones or bone meal may be beneficially given to Roses and Carnations. It is best applied to plants growing in beds or borders in spring—say February—and should be sprinkled round the plants, and be lightly forked in. Roses may have more than Carnations, and again strong vigorous plants should have more than weak ones, so no hard and fast line can be laid down as to quantity, but for Roses as much may be sprinkled on the border as will very lightly cover its surface. For pot Roses mix a peck of bonedust with two bushels of soil; half the quantity of bones will be sufficient for Carnations.—E. H.

Grapes Shanking.—*Sub.*—Grapes may shank from one of several causes. First, it may arise from debility through over-cropping; secondly, the roots may have penetrated beyond the border into wet, cold subsoil; and, thirdly, it may and often does arise from drought, although in a season like the last that is not likely. One thing is certain, shanking is due to a lack of support at a critical period, and a part—and sometimes a considerable part—of the crop fails in consequence. The cause must be ascertained before a remedy can be applied, and I should recommend first of all a thorough examination of the border. If the soil is wet, cold, and sour, and the roots in a fibreless, decaying condition, they must be lifted and the border re-made with new soil, improving the drainage.—E. H.

Devonshire.—The fruits were orange-red. Probably yours would turn so if placed in a gentle and dry heat.

Names of Plants.—*B.*—*Callicarpa purpurea.*—*Tenby.*—The *Veronica* is *V. decussata* var. *elliptica*; the other is undeterminable in its present state; send when in flower.—*W. G. D.*—No. 1 we cannot attempt to name from such a scrap; send when in flower; 2, apparently *Kalosanthes coccinea.*—*Anon.*—The Orchid flower sent is *Oncidium dasystyle.*—*Amateur.*—The leaves you send are those of *Cissis discolor*, which annually sheds its leaves.—*W. S.*—*Callicarpa purpurea.*—*M. F.*—1, *Nephrodium molle*; 2, *Adiantum tenerum*; 3, *A. hispidulum*; 4, next week.—*Orchids.*—1, *Zygopetalum maxillare*; 2, *Oncidium tigrinum*; 3, apparently a species of *Eria*, send larger specimen; 4, *Sophranitis grandiflora*—*X. F. Z.*—1, *Helleborus niger*; 2, *H. abchasicus*; 3, *H. niger* major; 4, *H. guttatus.*—*R. F.*—*Plumbago rosea*; the other is a fine variety of the same, named *superba*—*Enquirer.*—1, *Goldfussia isophylla*; 2, *Eranthemum pulchellum.*—*M.*—*Colechicum neapolitanum.*—*Decon.*—1, *Adiantum Capillus-venenus*; 2, *Asplenium Trichomanes*; 3, *A. monanthemum*; 4, *Ceterach officinarum*; 5, apparently *Woodisia hyperborea*—*X.*—*Aponozeton distachyon* (the Cape Pond-weed).—*Amateur.*—We cannot undertake to name varieties of *Chrysanthemum*; they should be referred to some specialist. The other plant is *Chrysanthemum frutescens*, but it is not the same species as the ordinary garden kind.—*M. R.*—The fruits you send belong to the Spindle Tree (*Eunymus europæus*). The flower is a species of *Aster* which we cannot recognise.—*S. T.*—*Bouvardia Humboldtii.*

Names of Fruits.—*Pears.*—1, *Passe Colmar*; 2, *Beurré Superfin.*—*Apples.*—1, *Golden Knob*; 2, *Cox's Orange Pippin.*—*G. W.*—1, *Louise Bonne*; 2, apparently *Colmar d'Été*—*Apples.*—1, *Lenox Pippin*; 2, *Peasgood's Nonesuch*; 3, *Winter Pearmain.*—*S. M. D.*—The *Baldwin* is one of the kinds of Apple imported largely from America.

Questions.

WILL any reader of THE GARDEN kindly tell me when and where the following trees have borne fruit in Great Britain or Ireland: 1, *Salisburia adiantifolia*; 2, *Taxodium sempervirens*; 3, *Wellingtonia gigantea*; 4, *Glyptostrobilus sinensis*? Of No. 1 there is a grand tree at Longleat, and of No. 4 the largest specimen I have seen is the one at Kew.—F. W. B.

Leaves of Camellias Curling.—Will any reader inform me of the cause of the leaves of my Camellias curling? There is a good show of flower-buds, and the plants are in a temperature of from 40° to 50°.—AMATEUR.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

LEAFLETS.

Mr. Marnock once told me that he had planted in all no fewer than twelve thousand Cedars of Lebanon in his various landscape gardening operations, that is to say, exclusively in ornamental gardening. I thought of him the other day when looking at the garden front of Wilton House, so stately and so dignified wholly from the use of these Cedars and other hardy trees. It is marvellous how much can be done with a few trees and a carpet of Grass, especially when the "bedding rubbish" is cleared out of sight.

Mr. Frank Miles has, in building his new house at Chelsea, left a large receptacle in the masonry of a balcony for the growth of Lilies, of which he is an enthusiastic grower. This is a capital plan. There is no reason why certain portions of the walls of London houses should not be made hollow, and thereby form an excellent reservoir for plants.

Canon Hole is sunning himself in the beautiful Riviera, a land of lovely gardens and fields, smiling with flowers in the middle of our winter, and which, owing to being snugly tucked in at the foot of the sunny side of the Alps, is, although in France, a far finer winter climate than Italy, or Turkey, or many lands farther south. Here the Roses blow throughout the winter, and all the greenhouse plants have escaped in the open air, so to speak. I am sure the readers of THE GARDEN will rejoice to see his letters from this region of flowers.

Mr. James Backhouse informs me that he grew that noble Antarctic Forget-me-not (*Myosotidium*) many years ago, but lost it. It is to be hoped some of the seed sent to me will grow. Perhaps we shall require annual sowings of fresh seed of the plant to secure a continuance of it here, as I believe it is short-lived and probably will not ripen with us.

I see that it has been resolved that on and after the 6th of December Russell Square enclosure should be opened to the public every Saturday and Sunday throughout the year (weather permitting), from two till five o'clock up to the 1st of April, and during the summer months to remain open till eight o'clock every Monday and Wednesday in addition to the above-mentioned days. This is a hopeful sign, and we may perhaps, even in our own day, see these well-closed and well-railed squares open to the public, as in other lands not always supposed to be so enlightened as our own.

Russell Square is a fine open space, and contains some fair trees for London, which it is to be hoped will be saved. But gardening in London has, perhaps, the most distressing variety of the art that is anywhere known. It is, indeed, astonishing in its stupid wastefulness, continually planting, year after year, thousands of evergreens, certain to perish, and while they are perishing digging amongst them to help them on with a stubbornness worthy of some useful work. The line of houses (some of them important ones) on the east side of the Green Park well illustrates the meanness and the absurdity of London gardening, the exception being where a tree like the Plane gets its head above the scene of continual muddling.

I hear that Mr. Burbidge has already made very successful efforts to improve the collection in the College Botanic Garden at Dublin, and that his Orchids are making rapid progress; however, it is as an outdoor garden that one expects this to be rich and great, and there is no soil that I know of which is so conducive to the growth and vigour of hardy plants as that in the garden in question. I remember once seeing there that large and splendid Daffodil (*Narcissus maximus*), almost startling in its proportions, quite a yard high. A complete collection of Narcissi is being formed. I am glad to hear that Mr. John Bain, again in pretty good health, is occasionally seen enjoying a walk round a scene so long that of his labours.

What a home this has been for rare plants for many years, and what a loss it would be to Irish horticulture and Ireland if such a collection were to be destroyed. At one time there were rumours of a proposal to do away with this garden, which happily proved unfounded. It may be questioned if there are any ends to which a university can put its means more desirable than that of supporting a botanic garden. It not only facilitates the study of botany, but has great influence in spreading a love and knowledge of a variety of beautiful plants, shrubs, and trees in the country.

The idea was that one botanic garden was sufficient for Dublin, and so that may be, but the two places are essentially distinct, the soil being very different, and the vegetation also. I fancy this will be made more apparent in the future, Glasnevin having such advantages of glass, and the College garden such a fine soil for herbaceous plants, bulbs, and hardy subjects generally, with the exception of Conifers, for which the air is somewhat unsuited. We may then look forward to pleasant contrasts between the two gardens.

Mr. Burbidge tells me that Mr. Balfe is still very successful with his beautiful New Holland Pitcher-plants and Fly-catchers growing in his sitting-room, also the Killarney Fern in the house. It is to be desired that the practice of cultivating such rare plants would be more general. One hears of a whole flora being cultivated by people in the north of Europe in their rooms. Perhaps it is because our outdoor gardens are enjoyable for such a long time during the year that we do not make so much use of our rooms for cultivating plants. I hope Mr. Balfe will tell us some day how he grows these charming plants indoors.

Referring to the illustration of Longleat in the last GARDEN a friend writes:—"Please turn to Loudon's 'Encyclopædia of Gardening,' ed. 1835, p. 315, and you will see a bird's-eye view of the bare house at Longleat on a plateau of farm land with formal rows and avenues of trees and whole fields of what, when filled with flowers, must be the 'variegated eels, tricolored worms, and glowing tadpoles' of the squire's correspondent now in the Riviera." Happily this is no longer so. This old way was the true one to destroy any beauty or variety a place naturally possessed, or which was added to it in the form of trees. Modern attempts to revive it have been disastrous in their results to the places where they have been tried.

I hear that Mr. George Maw is working very successfully at his Crocus book, which promises to be a very interesting and beautiful one. It will no doubt make these lovely flowers more accessible and better known than they are to a great number of people, and we must all wish Mr. Maw health and strength to work long, and with like success in similar ways.

So Mr. Serjeant Cox is no more. A diligent worker, he was one of those busy men with many cares who amused himself in his few hours of repose with his garden and flowers. He was an enthusiastic Orchid grower, and had a very good collection. He was proprietor of various journals, among others of the *Field* newspaper, which in his hands attained to such a high standing and to such great success. He presided at the annual dinner of the Gardeners' Benevolent Institution.

I had the pleasure of seeing Mr. Bennett's Roses at Stapleford the other day, and, although it was a dull time of the year, I was charmed to see the number of little plants of Tea Roses bearing large and handsome fruit, and all in rather small pots. He has certainly succeeded in seeding the Teas freely, and in raising new kinds should be many years in advance of all others, even if they acquired the same facility in getting the plants to seed.

Mr. William Newton, of Newark, gives me a glowing account of an orchard house he has seen at Drumlanrig, and which he describes as being something most remarkable both as regards building, culture, and the results already obtained. In such a wet climate an orchard house of this type must be delightful and most useful; however, wherever Mr. David Thomson is, there one expects to hear of great things in gardening.

M. Godefroy Lebeuf, of Argenteuil, tells me that he has just received a quantity of seeds of the new hardy rosy *Nymphaea*—a fact which may be interesting to some of my readers who love hardy flowers.

I see that Mr. Meehan says "the Cambridge Garden is a long way ahead of anything of the kind in America. The Bartram Gardens have little to boast of but a few valuable old trees. Fairmount Park has done wonderfully well considering how rarely a body under political influences comes to much. Mr. Shaw's garden, considering that it is the work of one man's lifetime, is a rare monument of success. It could hardly be expected to compete with an old institution like Cambridge. In short, Cambridge well deserves the honour of being the best botanic garden in the United States." No doubt it is so, and yet when I saw it it was a poor ramshackle affair made after the very poor models in Europe, and without a feature of any particular interest. In this respect it differed much from some of the public parks in America, which are quite equal to anything in Europe.

Mr. Peter Barr promises us some charming novelties among bulbous flowers during the coming year, and no doubt he will keep his word—such is his enthusiasm for these plants and such the extent of his collection. The pursuit of science, however, even in the case of the pursuit of flowers, has certain limitations, beyond which it is not very agreeable to pass. When Mr. Barr has to arrange to his satisfaction the synonymy of the species of a neglected family his society should not be sought by those who desire any peace of mind.

One of the reigning beauties exhibits, it is said, a praiseworthy moderation in the use of jewellery and flowers as personal ornaments that might well be imitated by those who make an extravagant use of these for "head dresses" and personal decoration generally. Some ladies' heads are very profusely ornamented with flowers and foliage, and at balls the skirts of their dresses are sometimes over-laden in the same manner. Both look very wretched after exposure to the atmosphere of the drawing room for a short time.

That is a good idea of Mr. Richard Smith, of Worcester—selling Apple trees with Mistletoe growing upon them, and it will take. The Mistletoe is certainly a novelty in the north of England, and more so in Scotland, where it is sometimes cultivated as an interesting object on a lawn. Though it seldom extends or propagates itself naturally there, it grows well when established on the Apple or Thorn, and we have seen it almost usurp possession of the stock in a garden near Edinburgh, where a fine bush of it has been in existence for many years.

Nothing, I am told by an eminent seedsman, amuses the trade more than the prejudices of gardeners on the subject of Hyacinth bulbs. Customers come to the shop and pick out the largest roots only, while others will only have the heaviest and pay no regard to the size. Both, my informant says, are mistaken in thinking they are securing the best blooms by their choice in this way. It is getting much like trying to determine the sex in eggs, but, as a rule, those bulbs which are high in the shoulders produce the best blooms, and it is said that the German bulb growers select these when they wish to produce fine examples of culture. Some of the ugliest and most lumpy-looking bulbs they say do best.

I read in a report of a meeting of the Royal Institute of British Architects, some words of the president, Mr. Charles Barry, which deal with the design for our Crystal Palace:—

"The real Paxtonian roof was not semi-circular at all, but flat, with what is called the ridge and furrow treatment; and the great building from which Sir Joseph Paxton got his fame was designed by him as a series of packing cases, one upon the other, and lessening as they rose, but always, of course, with horizontal lines. It was from my late father's persistent action on the Royal Commissioners for the Exhibition Building of 1851 that with some difficulty he induced them to see that a series of packing boxes did not produce a composition which was all that could be desired, and that it would be partially redeemed from monotony if it had a semi-circular roof over one portion; at any rate, in the centre. Again, when the Exhibition was at an end and the building was removed to Sydenham, he induced the directors of the Crystal Palace Company to extend the semi-circular roofs over the entire nave and transept, but this was only done after another fight, and after my father had shown conclusively from models the great improvement it would be, especially in such a situation. Well, the Crystal Palace directors did at last agree to it. I could not, therefore, allow the semi-circular roof to be called Paxtonian, because if Sir Joseph had been let alone it would not have existed at all, though he cordially approved of its adoption."

In the same paper Mr. John P. Seddon is reported to say, referring to street architecture—"Some of the best examples we have are ridiculously elaborate, and as over-architecturesque as the classic parodies of clerestories and triforia turned inside out, for instance, which can only be ludicrous. What we want is simplicity, and the omission of all the false ornament now stuck upon these houses; and until we succeed in these points we shall not have much good street architecture." This appears to me a sensible and much needed remark. Something of the same kind might be said of a good many examples of a certain school of landscape gardening.

"Sanitas" was at one time a cry of Lord Beaconsfield's; and if he will read the article by Lord Middleton in this month's number of the "Nineteenth Century," he will recognise the necessity for pushing forward a stringent Noxious Gases Bill next session. The state of the atmosphere in many parts of the country renders life almost intolerable—vegetation of every sort being destroyed, and the air for miles round thoroughly poisoned. The very moderate bill of last session ought not to have been suffered to "slide" like almost every other Government measure. *Truth* hopes that Mr. Cross will take up the subject in earnest next year. The pollution of our streams is

an evil too, though not so hurtful to vegetation as the pollution of the air.

I passed by Rollisson's once famous nursery at Tooting the other day, and saw the place in such utter ruin as I hope never to see again in the case of any such garden. The auctioneer had been there and left his ugly brand upon everything, even the dwelling houses and sheds, winter gardens, and glasshouses—all were in process of destruction. This nursery was at one time as full of interest as any in the country, and many good men as well as good plants went forth from it.

I see some beautiful specimens of the Newtown Pippin in our markets, and hear also that their culture is gradually extending to districts where they do better than in some of the old localities on the Hudson. I wonder was it a Newtown Emerson grew when he remarked one day, pointing to the pride of his orchard:—"That Appletree is worth more than my head to me. My income from the former is worth more than all my books to me."

Speaking of garden labels and tombstones I was amused the other day to see some of the old labels in Kensington Gardens which were really much larger than many grave-marks in certain cemeteries, being over 1 ft. across the face. There is thus room for fine bits of botanical pedantry on them, and they are mostly adorned with such an expression as "a Juglandaceous Tree." Mr. Gibson ought to look to this. He has a very good form of T iron label.

It is curious to observe the difference of taste exhibited by professed critics, and judges of florist's flowers, and the general public, more especially regarding Chrysanthemums. "What beautiful flowers!" said a lady lately at an exhibition of these flowers, admiring some large and rather loose blooms of what judges would reckon "coarse" varieties, "they are like ostrich feathers!" "I like these great woolly ones!" observed another lady, and numerous observations of the same kind showed that the ladies and the judges were anything but agreed on the "points" of excellence.

Probably the florist is to a certain extent right in his judgment of what constitutes a perfect flower; but those who admire flowers for their own intrinsic beauty, and are not trammelled by "recognised standards," sometimes see points of beauty that the critic in his artificial and severe notions of perfection may overlook. I observe that the judges of Chrysanthemums feel the blooms with their fingers very carefully, much in the same manner as a judge does a fat beast, and gives preference to those blooms that feel close and solid, and if the petals are all packed densely upon each other, as if pasted together, forming a ball of that peculiarly inartistic outline that denotes the highest art of the "dresser," it enhances the value of the flower.

A correspondent asks if my remarks in last week's "Leaflets" upon the subject of Chrysanthemums prepared for flower shows would not apply with equal force to exhibition flowers in general. The Azaleas, Pelargoniums, and even some of the Orchids are all open to the same objection, the prizes being generally awarded to those plants which most nearly resemble a decorated balloon, and the florist or amateur who has the oldest plant can generally win. If the judges were at liberty to award the prize to any plant which was the finest specimen grown in the natural way, so as to exhibit its beauties of leaf and form, as well as of flowers, we should gain in every way; and many true florists would

enter the lists who are at present debarred by the barbarous custom now in fashion.

The President of the Statistical Society (Mr. T. Brassey), in his opening address the other day, said: "The acreage of fruit land increased in England from 153,277 acres, in 1877, to 159,095 in 1878. Not a bad increase for one year, but the want of system in the work and the lack of preparation of the land often leads to indifferent results." The speaker then went on to say, and most people will agree with him, that the heavy outlay at the commencement, and the absence of any definite right with regard to compensation to tenants acts as a check to first-class fruit-culture. Men possessed of skill and capital will not plant for others to reap the crop.

A correspondent writes, "I often wonder why more care is not exercised in reading the proofs of some of our gardening papers. Only the other week one of the greater lights of the horticultural world called especial attention to *Trichonema suavis* as a pretty sweet-scented Orchid. If *Trichonema* was meant it is not an Orchid at all; but most likely the plant referred to was *Trichosma suavis*, which is an Orchid, and pretty, and sweet. Not long ago I saw the common Tuberose mentioned with the scientific (?) name *Polyanthus tuberosa* tacked on to it; shortly afterwards an unsophisticated amateur wrote me to ask if it could possibly be true that the Tuberose was a *Polyanthus*. I told him that although a Tuberose by any other name would smell as sweet, its proper name was *Polianthes tuberosa*, and that it was nearer a Lily than a Primula." I hope my correspondent has made sufficient allowance for the pressure more or less attendant on journalistic work.

GARDENING ILLUSTRATED is the most remarkable success of the year in its own way. I see it everywhere I go in distant parts of the country, as well as in the most unlikely places in London. It is the first thing of the kind that has really touched the great public as well as the specialist. Apart, however, from its mere success it is satisfactory to know that good practical information is brought by it into many thousands of houses. No such rapid success has ever been witnessed before in any journal of the kind, and it is a mistake to suppose that its success is owing to its cheapness, as more than one has been published at the same price before.

I read of a Texan river; its chief ornament is the beautiful Cypress (*Taxodium distichum*), 80 ft. to 150 ft. high, and 5 ft. to 10 ft. in diameter, a tree which likes to stand near the water, and to send its roots into it. The Cypress trees often stand so close as apparently to form a solid mass of trunks, and the tops to form a solid roof across the river. This is the tree of which there are such remarkable examples at Syon, and which, considering its great beauty and singularity, it is astonishing it is not made a more artistic use of in gardens and parks. A well-placed group would in time be superb. The effect of the Cypress woods is wierd and striking in the extreme.

"Mrs. Grant says that the General once lost all his money in a Potato speculation. He paid 750 dol. for 150 bushels of new kinds, planted them, expecting to make a large profit, but when they were ripe, Potatoes were too cheap to pay for the digging." It is to be hoped that the advent of new kinds among us is not attended with such sad results.

JUSTICIA.

Country Seats.—We shall next week publish a fine engraving and full account of Golder's Hill, the residence of Mr. Spencer Wells, perhaps the most beautiful garden, as regards design, in or near London.

THE INDOOR GARDEN.

JAPANESE CHRYSANTHEMUMS.

WHEN Mr. Fortune introduced his first batch of Japanese Chrysanthemums, and they were seen at one of the meetings of the Royal Horticultural Society, they took everyone by surprise. It was while at Yeddo, in the autumn of 1860, that Mr. Fortune saw for the first time the peculiar forms of this flower which are cultivated in Japanese gardens, and he collected about thirty different varieties. During their progress home to England a number of these were lost. The late Mr. John Salter, of Hammersmith, was the first to obtain seed from them, and the plants obtained from this were found to reproduce, as Mr. Douglas states (p. 492), nearly all the varieties lost on their transit to this country. Mr. Fortune was led to think that in course of time all the remarkable varieties of the Chrysanthemum seen by him in the gardens at Yeddo, and probably many more, would be reproduced from the seed of the few kinds which he brought home to England; and he has lived to see this realised. I have just referred to a Continental plant catalogue, and found it to contain

if it were desired to have dwarf plants. Notwithstanding this tendency to grow tall, Japanese Chrysanthemums make excellent conservatory plants, and are to be recommended as such. The great variety of form found in this section makes them better adapted for general decorative purposes than the more formal incurved varieties, which show little change in the matter of shape. The fact that they bloom late is an objection sometimes urged against these Chrysanthemums, but some, at least, of the newer varieties flower earlier than the forms first introduced, and when properly managed can be had in bloom sooner than is generally supposed. But their late character is not without its advantages, one of these being that the Chrysanthemum bloom is prolonged to a much greater length, as it is stated some of them will not expand their flowers till near upon Christmas. But the house that contains the plants should be a structure artificially heated if the flowers are to be preserved from two damaging causes, wet and cold.

It is well to start early in the season with these Japanese Chrysanthemums, to grow them on fast and well into size, but not to draw them, giving them rich soil and every encouragement to make a vigorous growth. Whether two or three, or eight or ten flowering

Odontoglossum Londesboroughianum.

nearly 100 kinds. Some of the newer varieties that have been seen this season are remarkable for their fine characters. Especial mention can be made of Madame Lemoine, rosy lilac, large, full and handsome in flower; Fulton, rich bright golden yellow, very fine; luteum striatum, pale gold, with a cinnamon reverse to the florets; Mon. Ardenne, clear pink, very large and handsome; Oracle, large lilac-pink, extra fine; Ville de Hayne, orange cinnamon, with a golden reverse to the incurved petals; Orphée, reddish crimson, fine in colour; Mons. Crousse, orange red, with a golden reverse, very fine; and Reine des Beauties, fine crimson.

Of the older varieties James Salter is one of the best and most useful, flowering freely; Gloire de Toulouse, rosy-purple; Red Dragon, Fulgore, Fair Maid of Guernsey, Elaine, Harlequin, Sarnia, white, striped with pink; Peter the Great, rich yellow; Magnum Bonum, bright lilac, very fine; Beauté Parfaite, light rose; Dr. Masters, extra fine; M. Delaux and Cry Kang are all good. This by no means exhausts the list of good varieties, but it serves to indicate a fine and select collection.

Many object to the Japanese Chrysanthemum on account of its tall growth and lateness in flowering. But all are not so exceptionally tall growing, and a few days since I saw some pretty dwarf plants of James Salter, where the stems had been twisted round and tied to stakes, thus forming fine specimens carrying good heads of bloom. Other varieties, no doubt, could be similarly grown

stems be left to a plant, each should carry but one flower, all the other buds being removed. This is the way to have fine blooms, and growers feed with liquid manure or other stimulants, so as to secure size in the flowers and richness in the colouring. At a Chrysanthemum show the general public are always found crowding about the stands of cut blooms of these unique Japanese varieties.

R. D.

ODONTOGLOSSUM LONDESBOROUGHIANUM.

THIS is one of the most distinct species of a peculiarly attractive genus, and its beauty is such as to make it a welcome addition to all good collections of Orchids. It was introduced from Mexico by Messrs. Backhouse & Son, of York, about thirteen years ago, and first flowered in the Londesborough collection about ten years afterwards. Mr. Denning exhibited a plant of it in flower at the Royal Horticultural Society's meeting on Dec. 6, 1876, when a first-class certificate was awarded to it as a desirable new decorative plant. Mr. Denning, who first succeeded in blooming this species, informed me at the time that it has a singular habit of shedding its foliage, so much so, indeed, that it might almost be termed deciduous, and that it grows well in an intermediate temperature along with Lycastes and Zygopetalums. The pale green, glossy, pseudo-bulbs are borne at intervals along a stout rhizome, and are roundish-ovate,

supported at the base by five or six long, sheathing leaves. Each young bulb bears one or two leaves at its apex, as shown in the accompanying sketch, which conveys an accurate idea of its elongated growth.

The plant as first exhibited bore a long drooping spike over 2 ft. in length and bearing two or three fully expanded flowers and nine

O. Londesboroughianum, showing habit of plant.

or ten buds. The inflorescence was a simple one, but more recently a plant at Burford Lodge, Dorking, bore a branched spike of thirty fine gold-lipped flowers. Our engraving was made from a plant which bloomed at Messrs. James Veitch & Son's nursery at Chelsea, during the past month. The sepals and petals are nearly equal, are cucullate with undulated margins, and are of a pale gamboge yellow, having concentric reddish-brown bars. The reniform lip is over an inch in diameter and of a clear golden yellow in the type, but Messrs. Backhouse & Son have recently sent us a

O. Londesboroughianum var. pardinum.

flower, rather larger than usual, in which the lip is profusely dotted with brownish-crimson, as suggested in the accompanying illustration. This variety, it is proposed, shall be called "pardinum," a name which is sufficient to distinguish it from the less heavily barred type. The column is curiously curved like a swan's neck, and is devoid of the auricles so usually found at the apex of the column in *Odontoglossums*. The whole aspect, and especially the bright golden tints of the flowers, and

their brownish-crimson markings, is singularly like that of some of the larger-flowered *Oncids*, and in point of beauty it may be compared with *Oncidium varicosum* or *O. tigrinum*. In its native habitat this plant is said to be found "growing on unshaded rocks, the temperature in the dry season being 110° by day, descending to 55° at night"; in fact, a Red Sea broiling heat, and a cool night temperature within the twenty-four hours. Growing, as the plant is said to do, on sunny rocks, its rambling habit of growth doubtless enables it to find fresh rooting surfaces—a change of soil or feeding ground in fact—highly essential to its welfare. Its rocky habitat, and the scorching sun-heat to which it has been subjected "at home" may also account for its deciduous tendency, just as the *Phalænopsis Lowi*, which grows on sunburnt limestone rocks in Moulmein, is also deciduous, and doubtless from the same cause. Some African *Angræcums*, which grow in similar dry and sun-scorched places, actually fail to produce any leaves, and trust entirely to their broad, handsome roots in which chlorophyll or "leaf-green" is developed; and the plant is thereby enabled to carry out its functions without true foliaceous organs, which, though a rare occurrence in Orchids, is commonly the case in Cactuses and Euphorbias. Although the plant is thus sunburnt, I have no doubt that its long roots find shelter, in clefts and crannies of the rock, or among leaves and *débris*, where they are comparatively cool and moist. Its habit of growth is rather awkward to manage, and perhaps the best plan with this and similar rhizomatous species is to fix them on a board, so as to afford their stems support, a little peat and Sphagnum being provided for their root-growth. Any little extra trouble with this plant will be amply repaid if the result gained be its fine golden flowers.

F. W. B.

PALMS IN FRUIT AT KEW.

Most of the vigorous-growing Palms reach too great a stature to be retained in the majority of plant houses until they arrive at the adult state; consequently we rarely see them in fruit, or form a correct idea of the dimensions they assume when allowed unlimited space, unless we see them in their native habitat, or visit the large glass structures devoted to their culture in some of our leading horticultural establishments. On a recent visit to Kew Gardens, we noticed an unusual number both in flower and in fruit, which induced us to make the following notes, which may be interesting to our readers, especially to those who only know our best Palms as small pot plants. In the Palm House, on the west side, beneath the dome, the great Fan Palm (*Sabal umbraculifera*), a tree some 30 ft. in height, with a stem 15 in. in thickness, bears an immense loose cluster or spadix of berries in the green state, measuring not less than 4 ft. in length, which might be taken for a huge bunch of the Royal Muscadine Grape, with its shoulders looped up by lying over the adjacent leaf-stalks. The berries are less than 1 in. in length, and of a glaucous green, sparingly distributed on some of the twigs, but so thick on others as to appear as if fused into a solid mass. In the axil of a leaf a little below this the remnants of an old cluster was seen with jet-black berries. Had this Palm a more elegant habit in the young state, such a yield of seeds as this would have been of great value.

Beneath this, one of Wallich's Palms (*Wallichia tremula*), a plant with as yet no evident stem and several tall pinnate leaves, bears a branched drooping spadix about 2 ft. in length, with its point touching the ground, the branches of which are thickly studded with oblong coral-red berries, varying in size from $\frac{1}{2}$ in. to 1 in. in length. So rarely do any of this genus fruit that this must be considered a novelty. Very near to the Sabal, and on the same bed, a noble specimen of the Chinese *Livistona* (*Livistona chinensis*, synonymous with *Latania borbonica*) carries two large spadices of fruit, which are given off just above the lowest leaves, and, having a stouter axis than the Sabal cluster, they stand out boldly from the trunk. The berries are about 1 in. in length, and taper to both ends, and in colour some appear to be grey while others are of a bright bluish-green. This tree is between 40 ft. and 50 ft. in height with a spreading crown of foliage. In a young state this is probably the best known of the Fan Palms. Close by is the finest specimen of Bauer's Palm (*Areca Baueri*) we have seen, rising to the height of 25 ft., with three spadices projecting from the stem, just below the leaves, in various stages of development. The largest berries are roundish, about $\frac{1}{2}$ in. in length, with a bright green skin and a black point; these ultimately become scarlet. The branches of the spadix show deep pits where the male and abortive female flowers have fallen away. Beneath this a slender-stemmed Palm, named *Synecanthus fibrosus*, with an elegant head of pinnate leaves, also bears three spadices—one bursting its sheath, another a little more advanced, and the oldest with both green and scarlet fruits, that appear to have reached their maximum size, about 1 in. in length, and in form oblong or ovate.

Next we came to a good specimen of the East Indian Wild Date (*Phoenix sylvestris*) with a stem 30 ft. or more in height, and about a score of spadices rising among the glaucous green foliage. These spadices have long flat stalks and heads like Grass whisks, with the twigs ornamented with oblong scarlet berries, which constitute the wild Dates. Near the central pathway a specimen of the singular spiny-fruited Palm (*Astrocaryum rostratum*) was seen with two erect spadices with the spathe or sheath arching over the male flowers, which appeared to have been dead some time, but the curious structure still remained and probably the mature fruits concealed within. A much larger specimen is growing near the north staircase with similar spadices. Within a short distance of this rises the Wine Palm (*Caryota urens*), the tallest tree in the building, over 60 ft. in height, carrying two spadices with recurved stems, the uppermost of which is fully developed and the lower in the act of bursting its spathe, and in the axil of a leaf lower down a third spadix is showing. The expanded one resembles an enormous tassel, and must be at least 6 ft. in length, with innumerable necklace-like strings of green flower-buds. This retrograde mode of flowering is characteristic of the Caryotas and Arengas. They grow rapidly until they reach maturity, but not necessarily their maximum size, as that depends chiefly on the supply of nourishment. When an inflorescence, which includes the spadix and its sheath, terminates the growing point and arrests further growth in that direction, they then produce spadices in succession from the axils of the leaves from the summit downwards until the supply is exhausted, when they die. Opposite to this on the north side of the dome, and towering above the other Palms, the elegant *Scaforthia* (*Scaforthia elegans*) supports a majestic crown of foliage upon a straight cylindrical trunk between 30 ft. and 40 ft. in height, and just beneath the lowest leaf sheath three large branching spadices of different ages with slender drooping white branchlets and green berries. This fringe of white produces a fine effect, standing out, as it does, in bold relief from the rich green foliage of the Bamboo in the background. On the adjoining bed the Excelsior Fan Palm (*Thrinax excelsa*), a dwarf tree with silvery radiate leaves, bears a paniced drooping spadix, retaining a few round white berries, the larger part having fallen.

Close by, the New Zealand Cabbage Palm (*Areca sapida*), produces three short branching spadices, similar to those of Bauer's Palm, but much less, with conical, bright green berries. In the north wing of the house, the Spreading *Ptychosperma* (*Ptychosperma patula*), a dwarf, ornamental Palm, is an attractive object by reason of its richly coloured spadices, which are produced below the leaves as in the *Areca* and *Scaforthia*. The oldest of the spadices has coral-red branches, with a row of oval yellow berries on each side; the younger ones becoming coloured. Other Palms were also showing their inflorescence, viz.:—Cuming's *Caryota* (*Caryota Cumingi*), a dwarf Palm just projecting its terminal spadix; the fur-leaved *Caryota* (*Caryota furfuracea*), rather less than the latter with its terminal spadix opening; and the *Caryota*-leaved *Martinezia* (*Martinezia caryotefolia*), a slender spiny-stemmed Palm, somewhat like the *Astrocaryum*, but instead of its spadix being surrounded by a hood-like spathe, it is enclosed within a long, flat pod-like sheath. In the Aroid house, which is devoted to Aroids and shade-loving Palms, such as Calami and *Chamædoreas*, we noticed specimens of the graceful glaucous-leaved *Chamædorea* (*C. glaucifolia*), of both sexes, bearing spadices which were quite as fragile as the foliage; the cross-leaved *Chamædorea* (*C. erueifolia*), with its slender 20 ft. stem, surmounted with a crown of Grass-like foliage, and five drooping male spadices; Hartweg's *Chamædorea* (*C. Hartwegi*), with flowering spadices of both sexes; Sator's *Chamædorea* (*C. Sartori*), with spadices of both sexes in various stages of flowering; Decker's *Chamædorea* (*C. Deckeriana* or *Morenia Deckeriana*), with female spadices; the elegant *Chamædorea* (*C. elegans*) and the small-leaved *Chamædorea* (*C. microphylla*), both with female spadices; but the most remarkable were two female spadices of *Chamædorea Ernesti-Angusti*; these were simple bright scarlet rods, which rose 2 ft. or so above the dark green leaves, with deep pits, and a few adherent blue berries. The male spadix has a very different appearance, being finely branched, and bearing numerous minute yellow flowers. The *Chamædoreas* have the sexes on different individuals, the male spadices have a drooping habit, while the female spadices are more erect, with a stouter axis.

There were also several Rattan Cane Palms (*Calamus*) in fruit. In these the axis of the spadix becomes elongated into a long spiny whip-like appendage, called *flagellum*, so as to place its branches at some distance apart. *C. viminalis*, *C. leptospadix*, *C. erectus*, and *C. pachystemonus* showed this structure remarkably well; the appendage of *C. erectus* was some 15 ft. or so in length; the fruits which were borne by *C. pachystemonus* were about the size of Peas.

To the student of botany or horticulture these fruiting Palms should be of great interest as affording examples of the fruits of four of the principal divisions of the Palm family, which include eighty

per cent. of the Palms that are to be found in our gardens. The *Areca* tribe is well represented by *Scaforthia*, *Caryota*, and *Chamædorea*; the *Calamus* tribe by *Calamus*; the *Corypha* tribe by *Phoenix*, *Sabal*, and *Livistona*; and the *Coco* tribe by *Astrocaryum*, and *Martinezia*. The *Borassus* tribe, which is not represented in fruit, includes *Latania* and *Geonoma*. G.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Hardy v. Tender Plants.—A great many of our most popular cultivated plants have only a fictitious value, which they maintain just as long as they are dear or difficult to grow, and gardeners and professed cultivators lend themselves to the deception more than any other class; ordinary people who love flowers for their own sake distinguish more clearly in such matters. Many of our so-called "fine" stove plants and Orchids are positively inferior to some of our commonest hardy border plants that not long ago were in danger of being lost through the indifference of cultivators. If the old *Coleus Verschaffelti* had only been a difficult subject to cultivate, and still selling at a guinea a piece, it would yet have been a much-admired plant, whereas it is now disregarded; and the same could be said of many other things. The much-lauded *Gardenia* is inferior to a good Pink or Carnation, and cannot approach a Rose; but some spend as much on its special culture as would keep a small garden, chiefly because it is rather hard to cultivate successfully. That popular Orchid *Calanthe Veitchi* cannot equal a good *Pentstemon* or a *Snapdragon*; but the roots sell for a guinea or more, and it is an Orchid, and hence admired. Its neighbour *C. veratrifolia* is inferior to a good white *Phlox*, but it is also an Orchid; a good plant would probably fetch £5 in the market, and it is revered accordingly; on a herbaceous border it would look positively insignificant. Not a few of our most noted stove and greenhouse shrubs are inferior to a Flowering Currant or a *Deutzia*, but the one is admitted to the drawing-room and the other is not. The *Bougainvillea* cannot compare with Paul's Scarlet Thorn or the *Pyrus Malus floribunda*, but gardeners adore the former and take no particular notice of the latter. The *Bougainvillea* will, however, get out of favour if everybody gets to understand its culture. These are only a few examples of a false taste that is not creditable to us.—J. S. W.

Browallia elata.—It is not a little surprising that the value of this plant, briefly alluded to in THE GARDEN (p. 471), has not been more generally recognised. If I am rightly informed it was introduced into this country from Peru in 1768, consequently is very far from being a novelty; yet it is seldom seen, especially grown as a pot plant for winter work. Its requirements are few and of the simplest description. We sow the seed thinly in pans any time during April, and it readily vegetates in a gentle heat. The seedlings are potted off singly into small 3-in. pots when large enough to handle, and returned to gentle heat till established, after which they are transferred to a cold pit or frame. After a few days they are pinched hard back, and when commencing to grow afresh they are shifted into 5-in. pots, the size in which they are to flower. Any common soil will suit them; we usually employ turfy loam with a little rotten manure and sand. During the summer months no covering is needed for them, but they are kept regularly watered and pinched back till a good head is formed, discontinuing the latter operation early in August. They are housed in September in common with many other plants, some being put into an intermediate house, to be followed later on by those put into a cool house, the object in view being to keep up an unbroken succession, as they do not flower well under cool treatment. With the help of liquid manure they can be had in bloom throughout the winter and spring months. We grow them principally for cutting purposes, the brightness of their small blue flowers rendering them very suitable for lightening up vases, &c. It is best when cutting to clear off one or more plants as required, and these will soon push out another supply. Has any of the readers of THE GARDEN grown the white variety, *Browallia elata alba*?—AN ESSEX CULTIVATOR.

Azolla caroliniana.—This charming water plant, allied to *Salvinia*, should become a favourite for indoor aquaria. It floats on water quite free of soil, sending down roots as the Water Lettuce (*Pistia stratiotes*) of tropical countries does, and, compared with that, it is much more easily cultivated in a moderate temperature. The tufts of delicate green leaves appear like tiny emeralds, and massed together form one of the choicest of jewels. At this season it requires all the light it can have, and should be near the glass in a moderately dry atmosphere. With the light of summer, no degree of atmospheric humidity appears to injure it, but now, during dull weather, with an excess of moisture, it dies off. All the living points must be carefully picked from the dead parts behind, and should be placed in clean water on which to float. A bell-glass is the most convenient

vessel in which to keep it, and if placed in a frame warmed with a pipe or in a greenhouse it will quickly revive. During summer it will grow out-of-doors, but then it becomes bronzed, and perhaps it is prettier when light green, as it is in the greenhouse or window.—L.

Standard Chrysanthemums.—Looking over the Richmond Show, held at the Castle Hotel on the 18th ult., I was much struck with the beauty and elegance of the standard Pompon Chrysanthemums, displaying, as they did, large heads of flower with a minimum of close training. For this purpose the larger Pompon section seems to be specially adapted. A fine head of Julie Lagravère, very telling as it is in the daytime, is a glow of rich crimson by gaslight. The chief drawback to standards is the bare stems, but a few Ferns or other fine-foliaged plants would make for them a capital hiding-place. The stiff, formal, trained show specimens are an abhorrence, but these semi-trained standard heads peeping out from a mass of Fern greenery are really beautiful.—A. D.

Marigolds Indoors (p. 453).—I can strongly recommend these for growing in pots for the embellishment of greenhouses and conservatories at this season. We have several varieties now in flower, which, interspersed with Chrysanthemums, Salvias, Eupatoriums, Schizostylis, late Pelargoniums, &c., have a most telling effect, affording, as they do, such a striking contrast in colour. The one in most favour here is Dean's Dwarf Yellow, which has medium-sized blooms; and these the plants put forth in the greatest profusion, and, not being large, they are most useful for cutting. As

Marigold "Meteor."

is the case with most soft-wooded subjects of a kindred nature, Marigolds do best planted out in a sunny position, where they can be kept well watered and attended to by way of stopping the shoots, and then lifted and potted up in the autumn, when, if kept for a week or so in a cold close frame, and heavily syringed, they soon get hold of the fresh soil and scarcely feel the removal. Grown and treated in this way, they are not anything like the trouble they are when confined to pots the whole season, involving, as they do during a dry time, much labour in watering.—S. D. [The above illustration represents a pretty variety of Marigold called Meteor, in which the florets are pale lemon edged with deep orange, colours which render it very effective. It has been exhibited at South Kensington two or three times lately. For the opportunity of figuring it we are indebted to Mr. H. Cannell, of Swanley.]

Standard Pelargoniums.—"A. D." (p. 459) strongly recommends these, and at the same time deprecates stiff and formal training. Now, according to my idea, a standard Rose, standard Chrysanthemum, or a standard Pelargonium, mounted on a long bare stem, is about the most unnatural object with which we have to deal now-a-days. Why should we disagree with the Japanese, as regards their dwarfing noble trees and shrubs, and yet hold up to admiration an equally absurd mode of culture? I am myself a great admirer of the Pelargonium family, and agree with "A. D." that the old Unique, and all the Ivy-leaf section are beautiful objects for indoor decoration, but I trust that neither he nor any other admirer of them will endeavour to revive the standard form of growing them; they are, as he remarks, beautiful in hanging baskets, and I may also add as pillar or wall plants, or for garnishing the edges of plant stages; but deliver us from the standard form of Pelargonium, except as a curiosity.—J. G. L.

Bouvardias at Clapton.—For winter flowering more healthy and luxuriant plants than those now coming into bloom at Messrs. Low's nursery it would be difficult to find, the foliage being broad and lustrous, the wood vigorous and well set with bloom, the general appearance of the plants denoting that throughout the growing season they must have been in the enjoyment of all the conditions necessary to perfect development. The unusual luxuriance of the plants in question would favour the belief that they must have been planted out during the summer months. Such is, however, not the fact; on the contrary, they were shifted on in the ordinary manner, and the pots are now crammed with healthy roots. Plants thus established are, for many reasons, preferred at Messrs. Low's to those which have to be potted up at a late period. It is commonly supposed that only by means of planting out can Bouvardias of first-class quality be grown; but the plants in question afford ample proof that such a practice is by no means necessary. In the case of all plants destined for winter flowering it is undoubtedly a great advantage to have the pots well filled with roots by the end of the growing season; and it is certain that, if this advantage can be obtained without in any way detracting from the luxuriance of the plants, planting out is a mistake. First-class blooms can only be produced by plants having a potful of roots in a healthy condition. When, therefore, the soil is matted with fibres, and development during the winter months is assisted by constant gentle warmth and free ventilation on favourable occasions, there can be but little doubt as to the result. The Bouvardia, like the Cyclamen, appears to luxuriate during the dull months of the year in a warm equable temperature, where it may at the same time be in the enjoyment of a free circulation of air. On the occasion of my visit to Messrs. Low's, the air was by no means warm, but the ventilators were open, and the pipes being gently heated, a light buoyant atmosphere was created, highly favourable to the development of the flower-heads and the expansion of the individual blooms.—J. CORNHILL.

THE KITCHEN GARDEN.

THE CHAMPION POTATO.

MR. SYME, of the Lawson Seed and Nursery Company, says—"The Champion Potato has been most appropriately named for, in Scotland at all events, it has thoroughly beaten every other variety in disease-resisting properties, and has lately been lifted at the rate of 10 to 12 tons an imperial acre, grown as an ordinary field crop. Having paid much attention to the Champion since it first appeared, I can fully endorse all that has been said in its praise, and certainly the past unfavourable season has proved it to be the most valuable introduction of the past few years. It originally came from Forfarshire, and, after trial, was recommended in the Lawson Seed List of 1875. In general appearance it comes between the Scotch Regent and the Irish Rock, embodying the good qualities of the former and the hardy constitution of the latter. Like other Potatoes its eating quality varies according to circumstances as regards soil, climate, and cultivation, but it may safely be classed among good table sorts. Those which we are using at home daily are pronounced by every body to be first class. The Champion is a strong rank grower, and should be allowed a fourth more space at least than that which ordinary kinds require in planting. It is, perhaps, the latest field Potato to ripen, the haulm remaining fresh when that of all others is withered. It should, consequently, be planted earlier than is usual for late sorts generally in order to do it justice. It will grow remarkably well on poor soils where other kinds would not succeed, and altogether it is highly recommended for a main crop in every garden and farm; it cannot, however, be too prominently kept in view that to fortify its disease-resisting character a thorough change of seed is necessary."

The Jerusalem Artichoke.—The scarcity of Potatoes will, in all probability, have the effect of again calling attention to this Artichoke as a substitute for them. Many objections have been urged against the Jerusalem Artichoke as a table esculent, on the ground of its watery character; but might not this be traced to some

extent to what might be termed the injudicious cultivation to which the plant is subjected? As a general rule, it is planted in an out-of-the-way part of the garden, in a shady and damp place, and has but little cultivation in the way of securing a good crop of fine tubers. This haphazard method can scarcely be conducive to the production of good tubers, and they may suffer in quality in consequence. The Jerusalem Artichoke will grow in almost any soil or situation, and in these respects it is a very accommodating plant; but as an old gardener once remarked, "To have fine roots it should be set in a rich mellow loam, in an open, airy part of the garden." He further recommended that, if the roots be large, they should be cut into sets, much as Potatoes are, each part to contain at least two eyes; and at any time during the month of March they should be planted in trenches, about 3 in. or 4 in. below the surface, the lines 2 ft. apart, and the sets 18 in. or so from each other in the rows. A good mellow loam, in his opinion, needed but little manure for the first crop, as they would be even in size, though by no means small, and of better table quality. When planted in this way, the stems will appear above ground by the beginning of May, when, as is usually the case with kitchen garden crops, a little earth should be drawn up to the stems and the ground kept clear from weeds. It is a very prolific vegetable, and a small piece of ground able to sustain the crop will produce a large quantity of tubers. By the beginning of November the stems wither, and they should be cut off to within a few inches of the ground; the tubers can then be dug up and stored, much in the way Potatoes are, or, as is commonly practised, they can remain in the ground and lifted as wanted. Opinions certainly do differ as to the table quality of this esculent; but as a modern writer remarks: "Strange as it seems, in those establishments where the best cooks are employed, this vegetable is almost invariably extensively used, and we have the strange phenomenon (in this country) of the richest families using the greatest quantities of the cheapest vegetables that can be grown. Such evidence as this, therefore, affords us ample excuse for endeavouring to induce the most prejudiced to give the plant a fair trial, feeling assured that sooner or later it must become, and especially among cottagers, a product of prime importance." Sometimes, at horticultural exhibitions, those who are called upon to award prizes to collections of vegetables look upon the presence of this Jerusalem as a weakening item; but if the tubers are of good size, even in shape, and handsome in appearance, they should carry the same weight as a good dish of Potatoes; and it is not fair for judges, as they sometimes do, to condemn an esculent simply because they do not care for it as an article of food.—R. D.

Wood Ashes and their Uses.—During the past year we have had ample means of testing the value of wood ashes or charred earth, both as a means of warding off the attacks of slugs and other garden pests from tender vegetables, and as a means of enriching the soil and consequently accelerating growth. I believe that the old remedy, fresh slacked lime, if used in excess, is positively injurious to some crops, and after it has lain on the damp soil a short period it loses its burning character, and then slugs pass over it with impunity. We have therefore been compelled to use ashes of every kind, but more especially those from wood fires; and now we convert every kind of garden rubbish into ashes. At this season of the year, when the thinning of shrubberies is generally receiving attention, any and every kind of trimmings may be converted into valuable ashes, as when once a good bonfire is kindled and a glowing red heat obtained—no matter how green the wood and leaves may be—the fire will burn away as fiercely as the driest straw stack if kept constantly fed with fresh material until the whole is consumed; and there is no more certain way of getting rid of noxious weeds, such as Couch Grass, Bindweed, Docks, &c., than that of passing them through the fire, as it destroys all seeds that generally abound in rubbish heaps that are rotted away by the slow process of fermentation. To get the full benefit of all their good qualities, the ashes should be kept quite dry, by removing them, as soon as they are cold, to a shed, there to remain under cover until required for use. Ashes are invaluable mixed with soot, coal ashes, and lime, for dusting over any kind of seedlings or freshly planted garden crops, especially of the Brassica tribe; while Turnip crops are especially benefited by such a mixture; in fact, the only limit to the many uses to which ashes may be put is the power of procuring them in sufficient quantities. We find them to be the best and safest of manures for mixing with new Vine borders, also with the potting soil for many exotic plants. If many of the so-called artificial manures were composed exclusively of pure wood ashes purchasers would have less cause to complain than they frequently now have; for, in the open quarters devoted to vegetable culture, the spots on which rubbish heaps have been burned are always indicated by the luxuriance of succeeding crops. We may not get another such exceptional season for slugs for some time, but I would strongly advise all growers of vegetables to have a good supply of ashes in readiness for the next seed time, and to apply them liberally to all crops directly they are planted or coming

through the soil, as nothing looks worse in a kitchen garden than irregularities amongst crops, and if not required for that purpose they will well repay the labour by promoting a healthy and luxuriant growth. They enrich poor soils and render heavy and retentive ones friable, and they may be applied without fear of injury to the most delicate of crops. Under glass we find they are extremely useful for dusting Cauliflower and Lettuce plants, and for mixing with the soil for forced Potatoes, and such early vegetables as are usually forwarded before their ordinary season out-of-doors.—J. GROOM, *Linton Park, Maidstone.*

The Black Radish.—On walking through the Halles Centrales in Paris early last month, I was puzzled with a black root about the diameter of a medium-sized Parsnip, and one-half its length. On purchasing and peeling one I found it was the Black Spanish Radish, which is either eaten alone or sliced thin and added to salad like Beet-root. It has a pleasing nutty flavour, and is about as hot as the common breakfast Radish.—D. T. FISH.

Watercresses in France.—The use of these seems almost universal in France, and the quantity consumed is enormous. The great markets are crowded with them, and they are almost universally used in salads, and much employed as a garnish for different dishes. With plenty of Endive, abundance of Watercress in a dash of oil, and a few slices of Beet, the Parisians make a most excellent salad.—D. T. FISH.

Decayed Tomatoes.—The taste for Tomatoes does not seem to diminish with the decline of the season. But the public should look at what they eat. Immense quantities of Tomatoes in London now are much decomposed and of very doubtful wholesomeness. The yellowish-brown spots which indicate decay are not often noticed by the consumer.—V. J.

Thousand-headed Kale.—I have for many years cultivated this Kale, which was brought into notice in Kent by the Messrs. Russell, and have found it a most valuable spring food for sheep. During last spring, when greens of all kinds were scarce, I had the satisfaction of being able to let a large number of workmen pick freely from a patch of this for the use of their families, and it proved most acceptable. I heard of its produce being sold at £50 an acre for the London market. Some people thin out to intervals of nearly 3 ft. between the plants, and grow them very strong and stalky. I prefer about half that distance, and at the present time I have 2½ acres of it, which promises an abundance of food in March and April. No frosts appear to effect it.—A. B., *Pluckley.*

Scarcity of Onion Seed.—I learn with regret that the Onion seed crop is this year a very bad one, and that seed will not only be costly next spring, but that its germinating quality will be questionable. This is bad news for all market growers, to whom the price of seed is a very important consideration, and not less for the consumers of Onions in all shapes and stages. One grower of seed told me recently that he had last spring planted three tons of bulbs that were then worth nearly £30, and that the entire produce would not exceed a few bushels—barely enough for his own sowing, as he is a large grower for pickling.—A. D.

Trebons Onion.—We prefer sowing this variety in the autumn and transplanting early in the spring; in fact, treating it in every way similar to the Tripoli varieties. Thus managed, it is very fine, much superior to those that are spring-sown; and although the crop was scarcely so heavy as that of the Giant Rocca, it was really of more value, as the latter has kept badly this season. Great pains were taken with the harvesting of all the autumn-sown Onions, but the Trebons is the only variety that has kept good up to the present time. I quite agree with the remarks of "R. D." (p. 465) with regard to the mild and pleasant flavour of this variety.—AN ESSEX GROWER.

The Best Late Pea.—Having to supply as many late Peas as it is possible to obtain during the month of October, every year I have given all the reputedly best sorts for late crops a fair trial, and now, after three year's experience, it may appear strange that a very old Pea stands first on my list, and that is Hair's Dwarf Mammoth. I have never quite lost sight of this Pea, but for several years I allowed some of the newer kinds to take its place, especially for late crops; but the result was that they could not be depended upon, or our soil was not suitable, for I found the supply falling off; so I went back to my old favourite, and I now find that I have quite regained my old position of being able to gather a plentiful supply of green Peas when pleasant shooting is in full swing. To me this is a matter of some importance. We gathered our last dish of this old Pea on November the 8th, while Omega, which is the next best Pea for late sowing, ceased to bear after the middle of October. These two kinds were sown about the middle of June, both on the same day, and I need hardly say I shall still continue to stick to the old friend that has served me so well.—"Gardeners' Magazine."

THE FLOWER GARDEN.

RAMONDIA PYRENAICA AT HOME.

In all situations this is a very distinct and effective plant; although not so striking as some of the bright-coloured Primulas and Gentians, yet it is well worth growing on account of its distinct habit and abundance of bloom. It forms an evergreen rosette of blistered, wrinkled hairy leaves, which clasp the ground, forming, from the same base, a number of crowns clustered together: these in course of time force the centre ones from their original position, thus forming a large raised cushion. The flowers are borne on stems varying from 4 in. to 6 in. in height, each bearing from two to six flowers. The individual blooms measure over 1 in. across, and are of a rich violet-purple with orange-yellow centres. I have seen single rosettes with over twenty flowers fully expanded besides buds, and when seen in that state the effect is most satisfactory. It is rarely seen in good condition under cultivation, owing to unsuitable situations being selected for it. In the Pyrenees, where it is very abundant, it is found growing in almost every conceivable position on the Moss-clad stone just above the water mark of the mountain stream, on perpendicular cliffs amongst Grass on damp spots, and even on the bare rocks fully exposed to the sun, but in this latter position it forms puny specimens similar to what we see here. The most luxuriant plants of it are found on the ledges of perpendicular rocks where the roots can creep into the narrow fissures and secure abundance of moisture, which is essential to full development. It is generally found on rocks having an eastern or western aspect, but rarely in a southern or northern one. When found in a southern aspect there are rocks immediately in front of it, which screen it from the sun. In its native habitat it grows in every kind of soil, but under cultivation I find peat to suit it best, mingled with plenty of rough sand, or old pots broken up fine. It grows freely in this compost either planted out on the rockery in a shady moist spot between stones or in pots under a north wall plunged in sand. I have often wished I had an old half-decayed wall which I could cover with this plant. Under such conditions I am sure it would succeed admirably, provided the wall was naturally damp, and I could also plant with it the beautiful *Saxifraga longifolia*, which is one of the most beautiful plants belonging to the Pyrenean flora. I have gathered the two close together in the heights above Gavarine. I have found at different times several varieties of *Ramondia*: one with white flowers was exceedingly pretty. I wonder whether any of these now exist. About twenty plants of the white kind were distributed from the Hale Farm Nurseries some few years ago, and another variety with rose-coloured flowers; this I lost. These variations, however, are very rare. We may pass thousands of plants before we find one sufficiently distinct to stop our progress. A. P.

The Pyrenean *Ramondia* at home.

GYPSOPHILA PANICULATA.

I HAVE only just now returned home, after an absence of some days and your paper of Nov. 22 has come to hand. I have just read in it the remarks of Mr. Thomas Williams, of Ormskirck, about *Gypsophila paniculata*. With the single exception that the name is derived, as he says, from two Greek words, one of which ("Gypson") means chalk, and the other is the verb ("Phileo") to love, I must beg leave to be at issue with him on every point. I may perhaps premise that I am quite aware that *Gypsophila paniculata* is a mountain plant, and no doubt over many a chalky range it sends down its thick, tough roots far below, but I was never referring to anything of that sort when I made a very casual remark about it to "Delta" the other day, and I was altogether speaking of the culture of this plant in our gardens, and of the best way to manage it. Because it is found on chalky hills, it by no means follows that it must be supplied with chalk in our borders; a great many other conditions may be wanting to make that of any use. As a matter of fact my experience with this plant was the following:—I first of all

put it in an ordinary border for herbaceous plants. It had what "Delta" calls good friable loam to depend upon, but it did nothing there. It soon became a stunted and miserable object, and, so far from having a root like that of an Oak tree, it looked as though it would before long have no root at all. It chanced, however, that I paid a visit to the garden of Mr. G. F. Wilson, at Weybridge, and there I was greatly attracted by a very fine specimen of *Gypsophila paniculata*. Its aerial gracefulness of bloom was something I had never seen before, and I immediately asked some two or three questions about it. Unless my memory very greatly deceives me, Mr. Wilson told me that it does well in peat, but whether he said as much as that or not, I am quite certain that one of the first things I did on my return home was to have *Gypsophila paniculata* removed from its bed of loam and peat into one of nearly pure peat. The effect was magical. It flourished and spread far and wide, so that the well-being of some neighbouring plants was endangered by it, and

it was a thing of beauty which could not fail to be admired. Let Mr. Williams only give it a trial of this sort, and I am sure he will forget all about the Greek derivation of its name, and he will put *Gypsophila paniculata* in peat for the future.

I am quite as much at a loss to follow him when he says that it possesses no qualities to make it a bouquet plant. I should say, on the contrary, that nothing so lights up a nosegay and gives it elegance and grace as a spray or two of *Gypsophila paniculata*. It is far better than any Fern I know of. I have over and over again given it away for this purpose, and its fitness has been admitted at once. I have not time now to hunt for the passage to which I allude, but I well remember that Mr. Ellacombe, of Bitton, called attention to this in one of the earlier numbers of THE GARDEN. I cannot divine why it should do for the grates in a dried state as Mr. Williams suggests, for it seems to me that it would then lose all its loveliness, and had better be consigned to the fire rather than to the grate. Altogether I am strangely at variance with Mr. Williams about this elegant plant, but I can only say I wish I had a great many "grand secrets" about other things on which I could rely with so

much confidence as I can upon the "grand secret" which I brought home from Weybridge.

HENRY EWBANK.

Ryde.

— I am of opinion that both Mr. Williams, of Ormskirk, and "Delta" are right about this plant, though neither of them are quite so. The plant is perfectly hardy, but it is capricious. I had it for some years in great luxuriance, but, having lost it, I have never been able to establish it again. Certainly it does not require, but it may do better in peat. I do not at all agree with Mr. Williams that "it possesses no qualities to make it a bouquet plant." When the Agricultural Society met at Oxford the first prize for nosegays in vases went to a bouquet which owed nearly all its lightness and excellence to sprays of the Gypsophila, so that I fully agree with "Delta" that "it is a most delightful subject for cutting for nosegays."—HENRY N. ELLACOMBE, *Bitton Vicarage*.

CHRISTMAS ROSES.

THE past wet summer appears to have just suited these, as I do not remember to have ever before seen the crowns so crowded with flower-buds as they now are, a circumstance no doubt owing to the foliage having been preserved so long in a healthy, free-growing condition, instead of being ripened off too suddenly, as is invariably the case if the weather sets in at all dry. Those who are fortunate enough to have good plants of *Helleborus niger maximus*, which is the best of all, will find them of great value for lifting and potting, to be used as window ornaments, a purpose for which they are well adapted, as there they are just at home, and last a considerable time in full beauty. Out-of-doors, even if the frost does not in a great measure spoil them, the blossoms become stained and discoloured; but in a window, or under glass, they lose that objectionable tint, and as they attain age are almost as pure as the Lily of the Valley. To have them in this desirable condition for cutting, it is a good plan to cover some of the plants up with hand-lights or large bell-glasses, under which they may be easily protected by throwing a mat over them, should the weather set in severe. The wonder is, considering their great decorative value, that Christmas Roses are not more grown, as in few gardens does one meet with more than a clump or two, and these generally in some out-of-the-way place, or smothered up in the herbaceous borders by other plants of much stronger habit. To do them well, they should have a place specially prepared for them in some sheltered spot, where, if the soil is sandy, loose, and open, so that their roots can ramify freely, they soon get to a large size, and emit a large number of flowers. Before planting, it is a great help to them to trench the ground, and work in plenty of leaf-soil and rotten manure, and when growth is active to mulch the surface around them, and give them a soaking or two of water, as the great thing is to get them to develop their foliage freely, for without an ample spread of this the crowns do not attain their natural size and strength, and therefore have not the power to bloom so profusely as they otherwise would. The safest and readiest way of propagating the Christmas Rose is by division, and the best time for doing this is in April, when the plants are commencing to send up fresh leaves. Dug from the ground then, they may be easily separated, after washing or shaking the soil away from the roots, so as to see clearly where the prominent crown buds are, and where a severance can be made without waste or injury to the other parts, which could not be done by making random cuts, or pulling them asunder without some previous examination. Plants purchased at once will yield some blooms, and will then be available for effecting an increase later on when their beauty is over. Although I have heard of seedlings being raised, I have never been able to save seed, as the pods have been always abortive; and yet they swelled and looked well filled till the time for ripening arrived, when they collapsed, and were found to be empty.

S. D.

Arum Lilies in Water.—A few years ago, I planted some pieces of this amphibious plant in water, by the side of an embankment, and they have so increased that, at the present time, they form an immense mass, 120 ft. long, and several feet broad, and, when in flower, they are a grand sight, hundreds of magnificent blooms being open at one time, and much finer than when carefully grown under the directions given in most gardening books. In severe winters, especially the last, they were cut down to the water's edge, but they always came up again as strong as ever when mild weather returned, and flowered well though much later than when not cut down by severe frosts. In very mild seasons they commence flowering before Easter. A good plan as regards planting them is, to fill some worn-out bushel baskets with any refuse soil that may be at hand, into this plant the Arums, and plunge them into about 2 ft. of water, then throw a few barrowfuls of soil and stones around to keep them

steady and to form mounds. The baskets soon rot, and the plants become masses of foliage and flowers, as has just been stated.—SANGUINEA.

Double White Rocket.—This should be taken up and divided every season, or it will soon cease to exist; a circumstance which may account for its being so rarely seen. For it certainly is one of the most beautiful hardy border plants in existence. Being very free its fine spikes of pure double white flowers, when grown in quantity, load the atmosphere with perfume; and when associated with the blue Canterbury Bell, one line of each, it has a striking effect. It will grow almost in any soil or situation, and it may be increased to any extent by simply splitting up the old stools with a sharp knife every autumn. We also grow the double purple, but neither that nor any of the other sorts, that I have seen, can at all compare with the grand old double white kind.—SANGUINEA.

The Fringed Grass of Parnassus (*Parnassia fimbriata*).—This interesting species has only recently been introduced into this country. It is a native of wet bogs in Nevada, Colorado,

The Fringed Parnassia (*P. fimbriata*).

&c., where it covers large tracts of land in the same way as the British species does in the north. It is a true perennial, forming a tuft of ovate-cordate, smooth, pale green leaves measuring from 1 in. to 1½ in. across, closely set together, and forming quite a rosette; from the centre rises a stem about 1 ft. high, bearing a solitary leaf about midway up, and terminating with a large Anemone-like flower, which is pure white and beautifully veined. The flower is composed of five petals having a narrow base or short claw, and the margins are beautifully fringed from the middle to the base, giving it a most chaste and elegant appearance. It is perfectly hardy, having stood out the whole of last winter on my rockery in company with *P. caroliniana*, *P. asarifolia*, and *P. palustris*, all of which flowered beautifully, affording a good opportunity of comparing their respective merits. *P. fimbriata* is one of the most beautiful bog plants with which I am acquainted. All the plants belonging to this group grow freely in spongy peat, leaf-mould, &c., especially if mixed with *Sphagnum*, in very wet positions.—T. S. W. [Our woodcut was prepared from a plant in Mr. Ware's nursery, Tottenham.]

Gaura Lindheimeri.—The striking effect produced by means of this plant in the squares and gardens of Paris induced me to raise some seedlings of it last spring with a view to giving it a trial in the flower gardens here. These seedlings have flowered abundantly, and I have little doubt that when this plant becomes better known it will prove a permanent addition to our stock of hardy bedding plants. It grows about 2 ft. high, and is of upright habit, and branches very

freely, every shoot yielding a succession of pinky-white blossoms, and with liberal treatment there seems no limit to the time during which it will keep on blooming. Planted in front of shrubs and in mixed arrangements of herbaceous plants, or in the back row of a ribbon border it would prove equally effective. Its roots freely from cuttings made of the young side growths, inserted at the same time as those of the *Calceolarias*, and treated in the same way through the winter months.—*J. ROBERTS, Gunnersbury Park.*

Fern-leaved Rue (*Ruta albiflora*).—The annexed representation of this exquisite plant was prepared from a spray furnished by Mr. Green a short time ago, from Sir George Maeleay's garden at Pendell Court, Bletchingly, where it has withstood the rigour of

(1) The Fern-leaved Rue (*Ruta albiflora*), half natural size.
(2) A spray, natural size.

the last winter unprotected. It may, therefore, be fairly considered to be hardy. It is a native of Nepal, and though more than a century has elapsed since it was first introduced, it is by no means a common plant in this country. Its finely cut foliage overlaid with a glaucous hue, and the profusion in which its tiny, bell-shaped, white blossoms are produced, render it a highly desirable plant. It is, moreover, one that requires only the simplest culture either in pots or in the open border. Mr. Green says it is not a little surprising that this Rue is so little grown, for it is not only valuable and graceful for autumn and winter flowering as a cool greenhouse plant, but it has proved at Pendell Court to be quite hardy and is in flower up to the present time. It also proved hardy some twenty years ago in the gardens of the late Mr. W. Borrer, Henfield, Sussex.—*W. G.*

Effect of the Late Summer on Hardy Plants.—A curious instance of the inclemency of the early autumn is that the

usual autumnal flowers failed to perfect their blooms in the north of England. *Statice latifolia* and *S. Gmelini* remained nearly two months in bud but never flowered. The Sunflowers, double and single, were stricken down by frost before any of them had produced more than one or two blooms; and the *Lilium auratum* only bloomed in open quarters; wherever planted in the shade its buds never expanded.—*BROCKHURST.*

ROSES.

THE ROSE ANNUAL.

MR. W. PAUL'S Rose Annual for 1879-80 has just reached us. It contains coloured portraits of *Pride of Waltham*, a delicate flesh-coloured Hybrid Perpetual, richly shaded with bright rose; *Masterpiece*, rosy crimson, also a Hybrid Perpetual; *Little Gem* or *Crimson Moss de Meaux*; and *Jules Chretien*, a velvety shaded deep red Hybrid Perpetual. In addition to these, it contains chapters on the current year; new Roses; the best Roses; Rose synonyms; correspondence, and observations on the Rose shows. From these we select the following, on

REMINISCENCES OF OLD FAVOURITE ROSES.

It is now over forty years since I had my first lesson on growing and exhibiting Roses, and on looking back what changes do I see. But some old faces are left still. The first Rose I remember is the common *Pink China*, growing in a sheltered spot in my grandmother's garden, a large bush, 6 ft. to 8 ft. high, covered with lovely buds almost to Christmas. And associated with this is a *Crimson China*, a lovely contrast. I presented, Nov. 12th, a bunch of these two sorts to a lady, who pronounced them beautiful. These old friends carry me to another lovely spot in an old-fashioned place, "Luton Hoo," the residence of the late Marquis of Bute. There were large clumps of evergreens encircled with these *Roses* and *Honeysuckle*; beneath grew in sweet luxuriance *Violets* and other dwarf perennials. Late one autumn I was walking through a Rosery of considerable extent, well screened with evergreens for a background, and close in front was a line of my old *Pink China*; scarcely a bud was to be seen on any of the other sorts in the beds but that line was beautiful. Closely allied to the above is *Mrs Bosanquet* and the old *Bourbon Queen*; and of later date, *Souvenir de Malmaison* and *Gloire de Dijon*, *Jules Margottin*, *General Jacqueminot*, *Duchess of Sutherland*, and *La France*; but none can compare with my old friend for constant and abundant blooming late in the year. At the time of which I speak, the *Damask* and *Gallica* were in high favour, and pretty and sweet they were, but of short duration.

This brings to my mind a journey I once took to a Rose show in Essex. I was up before the lark, waiting for sufficient light to start by, and we had a lovely lot of blooms, with plenty of buds in all stages of opening. The *Regent's Park Show* was on the same day, where we took the first prize for fifty blooms. But I had the cream of the lot to take with me into Essex, and I started with full confidence of an easy victory. The flowers rode well, and were in first-rate condition; but the judges placed me last, and several exhibitors complained that I had a prize at all. I staged the best H.P.'s and some beautiful Teas, but the other exhibitors' flowers were all *Gallicas*. Beaten by *Gallicas*! I returned home a sadder and a wiser man, having come to the conclusion that if I went to Rome I must do as Rome does. On leaving, I invited my friends, Cant and Hedge, to come to London, but to leave their *Gallicas* at home, and many will remember the fine Teas afterwards shown in London by Mr. Hedge. But, again, I pass through Essex to an adjoining county, with a collection of over a hundred varieties, all the finest sorts of H.P.'s, Teas, &c.; but my former competitors could not stand against me this time. The old standard of excellence had been lowered, and a new one created. The poor *Gallicas* had to give way, and I was awarded two silver cups, which were the first but not the last prizes which I won, for I have had five or six cups at a time when *Roses* were shown as one sees them on the tree with buds in every stage of opening.

I have passed from the list of exhibitors; but if I look in at the shows now, what do I see? Not what we gloried in, but lines of flowers almost as bare of buds as lines of *Dahlias*. But exhibitors must to a large degree all bow to the Goddess of Fashion, still we lose much that is most beautiful in Nature by the excessive disbud-ding now resorted to. But I must not forget my old friend, the pot Rose, as that was always a pet of mine; and at my first date, if we could get five or six blooms on pot plants, they were looked at with as much wonder as the mammoth specimens now exhibited. Well do I remember taking a standard of the *Smith's Yellow Noisette*, with ten blooms on it, to an exhibition; it was scarcely forward enough for the day, so we plunged the pot in a strong bottom heat in the Pine-stove, and that had the effect of opening the flowers in the best possible condition. This sort is at all times a difficult one

to open well, but many very full Roses open better with heat and moisture. And now comes the day to match our strength against the noted Lane. It was at the old Chiswick gardens. I thought we were safe for the first prize. But no! That glorious old Coupe d'Hebe was too much for us. The late Mr. J. Edwards told me on that occasion it was "a long Lane that had no turning;" so I nourished my pets with night soil and liquid manure as much as they would stand, and at Regent's Park my Paul Ferras and Paul Ricaut turned the scale, and once turned it was not then so difficult to keep it on my side. The smaller plants were always my favourites, such as can be grown in about 9-in. pots, in good strong loam, stable manure, and night soil, thrown together six months previous to use. The plants should be potted early in September, and started in gentle heat—a little bottom heat, if possible—and plants so managed will always reward one for the cost and trouble. The Rose-house was always my delight, and reminds me of my friend, Maréchal Niel. How I prepared his place with 2 ft. of good soil, well drained, and selected a strong 3 ft. standard with a free stock, started him growing in April, and he made a growth of 15 ft. the first year! Only three or four shoots were allowed to run, and these in pruning were shortened to about 10 ft. The shoots broke regularly by being bent down; and the next year I was rewarded with 300 lovely flowers on this one plant. By cutting out the old shoots in pruning, and encouraging the new ones in their place, every succeeding year this beautiful plant for several years presented us with a similar display of magnificent blooms. Although I do not now exhibit, I still cultivate Roses with all the ardour of former years, and far more extensively than ever, and experience gives me grander results!—WILLIAM IRONMONGER, *Framfield, Hawkhurst.*

Of the new kinds of 1878-9, those which Mr. Paul has selected as the best are:—Hybrid Perpetuals: Barthelemy, Levet, Gaston Leveque, Henri Vilmorin, Jules Chretien, Louis Dore, Madame Lilienthal, Madame Morane Jeune, Paul Jamain, Pierre Carot; Prefet Limbourg, Princesse Marie Dolgorouky, Souvenir de Madame Robert, Souvenir de Victor Emanuel (Moreau), and Wilhelm Koelle. Tea scented: Dr. Berthet, Innocente Pirola, Madame Etienne Levet, and Reine Marie Henriette. Noisette: William Allen Richardson. Amongst the Waltham Cross Roses, the Countess of Rosebery and Duchess of Bedford are stated to have proved two of the finest of recent novelties.

Rose Baroness Rothschild.—Of all Roses with which I am acquainted, this is the best for late blooming. Since the month of July we have been cutting from it weekly; and to-day, November 29th, I have cut a bloom from it equal to the best in July. How does this Rose succeed under glass in winter?—CAMBRIAN.

Noisette Rose Jaune Desprez.—What a delightful wall Rose this is, especially for unfavourable situations. It is wonderfully long-lived and vigorous. It is one of the earliest to open in spring, and one of the latest in autumn. Colour fawn, tinged with pink, strongly scented. It is an old Rose; I have known it more than twenty years; in fact, I am acquainted with a plant of it on a gardener's cottage twenty-three years old.—E. HOBDAV.

Climbing Roses for Trees.—Ayrshire—Dundee Rambler and Alice Gray, creamy-white; Ruga, pale flesh; Thoresbyana, white. Boursault—Amadis, crimson; Blush, pink; gracilis, bright red. Evergreen—Félicité Perpétuelle, white. Noisette (for trees of lower growth, such as partly dead Thorns or Hollies, short pollards, &c.)—Celine Forestier, yellow; Aimée Vibert, pure white; Rêve d'Or, deep yellow. Hybrid China—Charles Lawson, rosy-carmine. Tall climbers—Gloire de Rosemenes, single scarlet; Willison's Weeping, scarlet; and Willison's Victoria, pink.—J. CHALLIS, *Wilton, Salisbury.*

The Engraving of Longleat.—A correspondent writes to us as follows concerning this: "Allow me to thank you for your beautiful picture of Longleat. I am a little difficult to please, but I soberly and thoughtfully, and not without the memory which reminds me of many other excellent illustrations of English gardens, write down my conviction that this engraving from Parson's sketch is the best I have ever seen. The trees and distance are lovingly handled, and the repose of the untormented breadth of sward is a fit foreground to the stately Elms and the repose of the fine old house beyond. There is no pretence about the picture; it looks true, and, I have no doubt, is true to a tree trunk or a window. The magic of repose throughout satisfies me, and I shall often turn back to it with pleasure as a bit of good, honest art, and also for its admirable portraiture of an English residence and park. I feel like the man who smashed his fiddle after hearing Paganini, and so I think I shall never try to draw again."

THE GARDEN FLORA.

PLATE CCIX—A GROUP OF COLOURED PINKS.

Drawn by CONSTANCE PIERREPONT.

THERE are probably few cultivators of garden flowers who would be bold enough to say how long the Pink has been cultivated as an improved flower in this country; indeed, nothing definite can be ascertained as to the original species of *Dianthus* from which the numerous varieties of Pinks have sprung. I would be inclined to place the fine laced varieties, the colours of which are purple or purplish-red on a white ground in one section, and suggest that the original species from which they have sprung is *D. plumarius*; this is a dwarf-growing plant, introduced from the south of Europe as far back as 1629. Its flowers are white with a purple centre, and the leaves glaucous. The varieties represented in the annexed plate certainly belong to a different type, and very probably their parentage could be traced back to another species, namely, *D. deltoides*, which may frequently be found in pastures and grassy banks in many parts of Britain. The flowers are palerose, and are furnished with a circle of deep-coloured spots. Referring again to the flowers in the accompanying plate, *Lady Blanche* is the finest white variety yet raised; the flowers are sufficiently double to suit all tastes, and yet the pod does not burst. It is a very free-flowering sort; a single plant raised from a cutting in May will produce nearly fifty flowers the following season. Lord Lyons is certainly the best of the coloured varieties; it flowers very freely, and its blossoms are of good shape. In habit the plant is distinct and dwarf. *Ascot* is a very distinct flower, but lacks the symmetry of most of the others. *Derby Day* is a strong-growing variety, but rather straggling in habit, and subject to spot; it ought to be grown in every collection, but I do not place it high on the list as regards quality. *Newmarket*, a reddish-purple self, I have not grown, and therefore cannot speak as to its merits. *Miss Joliffe* is a flower of quite a distinct type from any of the above, and must rather be classed with the perpetual-flowering Carnations, although it differs from them in not growing so tall, nor branching much from the main stem.

There are a few other varieties which should be grown, and one of the best of them is the old but very useful *Anne Boleyn*, which I consider better than *Derby Day*; Rubens and Mrs. Pettifer ought also to be grown. The classification of these Pinks is haphazard, and not scientific. They are merely known as "early or forcing Pinks," although some of them are not early; still it is enough for most cultivators that they obtain the varieties which they require, and that they know how to grow them. They are most frequently used for forcing, and for this purpose the plants must be grown in the open ground during the summer months, and should be potted into their flowering pots in September or early in October.

It would be rather difficult to obtain large specimens of these Pinks to force for next season, but those intending to grow them would do well to obtain as good plants as possible this year, and propagate from them in May next season. If the plants are placed in gentle heat about the end of March, they will have grown sufficiently by the first week in May to produce good pipings or cuttings. The small growths should be taken off carefully and be inserted in fine soil in pots or shallow pans, about a dozen in a 5-in. pot. The pots must be plunged over a gentle hotbed, and if shaded from bright sunshine for two or three weeks, they will be rooted by the end of that time. When they show signs of growing, air must be admitted more freely, and after a time the pots may be placed out-of-doors. After this free exposure to sun and air, it will be desirable to plant them out about 6 in. apart on a bed of fine soil; here they will grow away freely and form compact tufts (perhaps bushes would be the more correct term) by the end of the summer. There will be some small plants amongst them, and pots of various sizes are used in which to place them for forcing. I generally use 5-in. or 6-in. pots. If the plants are small two or three are placed in each, but in a good season one plant will well fill a 6-in. pot. When potted arrange the plants near the glass in frames, and keep the lights rather close until the plants have become established, when air may be more freely admitted. They may also be wintered in cold frames, from which they are removed as required to the forcing houses. One of the best forcers is *Lady Blanche*, the flowers of which are also the most useful because of their being pure white. In forcing it is best not to have a very high temperature to begin with, and the plants should be placed near the glass, admitting as much air as possible, having regard to their requirements. When the first flowers open I like to remove the plants to the greenhouse, where the remainder expand slowly, and last in good condition for many weeks.

J. DOUGLAS.

[For the opportunity of figuring the blooms illustrated in the annexed plate we are indebted to Mr. Ware, Hale Farm Nursery, Tottenham.]

GARDENING FOR THE WEEK.

Conservatory.

Winter Arrangement.—There are few more effective plants for conservatories than Tree Ferns, but, in common with many of the dwarf-growing species, it is often supposed that the Tree kinds require considerably more warmth than that which an ordinary greenhouse affords, especially in winter; consequently, it is no unusual occurrence to see the large arborescent species confined to houses in which some heat is continuously maintained, and frequently much more than they like, whilst they would be better in every way in a lower temperature with a drier atmosphere. Even where the temperature of a conservatory is kept no higher than that of an ordinary greenhouse, there need be no hesitation about placing Tree Ferns in it. The arrangement of these and other plants of a similar description must necessarily be dependent upon the character of the house. Where objectionable central stages exist, such subjects as those of which I speak can never be made effective, as the pots or tubs in which they are grown have to be elevated, and are thus brought too prominently before the eye; and, unless the house is a high one, the heads of the plants, if tall, are in too close proximity to the roof, which not only interferes with their appearance individually, but spoils the general effect. Such kinds as *Dicksonia antarctica*, the more elegant *D. squarrosa*, *Cyathea dealbata*, or *Alsophila excelsa*, all species that form compact, moderate-sized heads, especially when not grown too hot, may be used in conservatories of not more than medium size, so as to form centres of groups, which are much more effective than the often adopted method of filling the middle of the house with a large single mass of plants. Individual specimens of such as I have named, with stems sufficiently tall, or that can be raised high enough to admit of walking under them, with a circle of bushy *Camellias*, *Cytisus*, *Acacia armata*, *Azaleas*, or anything of similar character, gradually reduced in height towards the margin, and edged with still lower things in or out of flower, produce an effect which the most costly and elaborate stages fail to give. The great advantage resulting from dispensing with centre stages in conservatories, or beds in which the plants are planted out, is that it admits of the arrangement being so varied from time to time as to give the whole a completely different appearance, so much more desirable than the continuity of the same plants always in the same places as when stages are used. Even in the dull season of the year that we are now passing through an eye that is trained to effective arrangement will, with limited and common-place materials, often make a conservatory or greenhouse look better than where more valuable plants with more flowering subjects are at command. But in all this kind of artistic grouping it is necessary to prepare much larger numbers of plants that are made to do subordinate duty in edging the groups than under ordinary circumstances, especially in the case of winter plants, such as *Primulas*, *Roman* and large-flowered *Hyacinths*, *Narcissi*, *Hotela japonica*, forced *Lily of the Valley*, small shrubs (such as *Deutzias*, *Azalea amœna*, and *Double Prunus*), *Richardia æthiopicæ*, *Spiræa palmata*, *Amaryllis*, and anything of a similar somewhat taller character, with enough green material, such as *Adiantum cuneatum* and *hispidulum*, *Pteris serrulata* and *P. cretica albo-lineata*, *Isolepis gracilis*, and *Selaginella*, all of which it is necessary to grow in greater quantities than for the promiscuous style of plant arrangement, beyond which at one time little was attempted. Where *Cyclamens* are well grown with the last year's sown plants kept on continuously warm with something like an intermediate temperature, these will now through the winter months, where grown in sufficient quantity, play an important part in the arrangement of conservatories and greenhouses that are kept tolerably warm, without which plants that have been grown with some heat cannot be expected to continue long in good condition; but to do justice to these plants they require keeping near the glass, so as to have plenty of light. Moveable wire stands are very useful wherein to group plants of this character, which, if relieved by a few of the hardier kinds of more elegant leaved *Palms* or other green-foliaged plants, do much to enliven the general appearance. There is one thing in reference to the management of conservatories at this season of the year of which it is well to remind the inexperienced, and that is the necessity for doing something to prevent the atmosphere getting too dry. This is a matter which requires to be carefully managed, so as to avoid the extremes of too much moisture, which is objectionable in many ways, and the dry arid atmosphere that never fails to cause the premature dropping of *Camellia* buds. Where the pipes for warming the house are sunk in trenches below the floor the best means that I have found is to get here some moisture-holding material, which, if kept wet enough to produce the slight evaporation necessary, will answer the purpose, and wherever the heating medium is placed something of a similar character can be managed in such a way as to answer every purpose.

Greenhouse.

Watering.—Simple as this operation is, it will nevertheless be found that in a mixed collection of plants moderately varied in character, it requires a good deal of attentive observation to give to the whole water in such proportion as may be required, for, although general rules may be given, such as impressing the necessity for plants of comparatively quick growth being more liberally supplied, not only when in active growth through the summer, but also during winter, than slow-growing, fine-rooted, hard-wooded subjects, some of which need no more water during the dull months than will keep the soil slightly moist; yet, to generalise too far in this direction is sure to lead to serious mistakes, as there can be no question that the state of the roots as to the moisture required, quite as much in the winter as in the summer, always depends upon the conditions, in this respect, under which the plants exist in their native country in the different seasons of growth and rest; for instance, *Azaleas*, coming as they do from the moist hill districts of India, though very fine, somewhat delicate-rooted plants, will not bear without injury the soil being kept nearly so dry as plants from New Holland or adjacent parts of the world, whilst many of these in turn need more water than some of the Cape species, particularly *Heaths*. Those, therefore, who have not had much experience in the cultivation of mixed collections of plants will find that they will be able to form a correct estimation of their requirements, by in this way determining the more or less moist condition in which they should be kept, than by being led alone by their hard or soft-wooded character. Taking plants collectively, both those that require keeping the driest, and also those that want the most moisture, there will obviously not be, in the winter season, danger of absolute death through their being kept a little too dry, as there is from a similar cause in the summer when growth is in an active state; yet where plants naturally need the soil about their roots being kept comparatively moist, when they receive an insufficient supply they get into a languid condition that enfeebles them so far as to prevent their making nearly the progress they ought when the season of growth comes round.

Primulas.—The single varieties of this plant have become much improved of late years; but still no attention to seedling raising has the effect of removing the disposition to damp off in the winter months, which there seems to be only two methods of avoiding. Of these the best is keeping them through the winter in a temperature higher than that of an ordinary greenhouse, say from 45° or a few degrees higher at night in a light position. Thus situated, with a little more warmth in the daytime, there is not much to fear from the effect of damp, and they may have sufficient water given to enable them to keep on growing and throwing up flowers; but when in greenhouses where little more heat is maintained than just enough to exclude frost, they need to be kept close up to the glass, and should receive no more water than is required to prevent the soil from getting so dry so as to stop all growth. Where there is a chance of treating them in the former way they will produce double the quantity of flowers; yet at the best the single varieties are of little use for bouquet or button-hole flowers, as compared with the double kinds, in which there is now even greater improvement than in the single ones. The facility with which the single varieties are raised from seed to that of the double sorts, needing, as the last do, to be increased by cuttings, is the cause of the double ones being so much less grown than they deserve to be. The fine forms of these that now exist are such that wherever there is a continuous demand for cut flowers, and means of keeping them something warmer than a greenhouse through the winter, they should be extensively cultivated. The best forms, now in the colours of pink, pure white, blush, and white slightly flaked with pink, have flowers almost as large as an ordinary *Pink* (*Dianthus*). The advantage in their use for cutting is that they will keep fresh for days, whereas the blooms of the single varieties are so liable to fall off that no dependence can be put on them in any arrangement of cut flowers.

Schizostylis coccinea.—Those who grow in pots a good stock of this handsome late autumn blooming plant cannot fail to have noticed how useful its bright scarlet spikes of flowers are through the autumn months. Its blooming will in most cases now be nearly over, and although the plant, so far as I have had experience of it, is hardy, still in common with anything of a similar nature that has been kept in a warm greenhouse through the autumn, it is better not turned out-of-doors, but should be moved to a cold pit or frame, and there have the pots plunged in ashes.—T. BAINES.

Flower Garden.

Auriculas.—It is still necessary to look over the plants in order to remove all dead and decaying leaves. Apply water to prevent the soil in the pots becoming quite dried up. I recommend mats to be placed over the glass when the frost is very severe. Admit plenty of air; in fact, remove the frame-lights

whenever the weather is at all favourable. There is some difference of opinion as to the position in which the frames should be placed. Most growers prefer them to face south or south-east, but much, of course, would depend upon the time when the plants would be wanted in flower. If the bloom is wanted to be at its best by the middle of April, I would say let the frames face the south, but if it was not wanted until nearly the end of the month, let the back of the frames be placed to the south. Seedlings continue to vegetate, and although severe frosts may not injure them much, I prefer placing the pots near the glass in a cool greenhouse. See that they just receive enough water to maintain a fairly uniform degree of moisture in the soil.

Carnations and Picotees.—It is singular how the soil in the pots of those plants that have been placed in a gentle bottom heat require so much water as they do at this season, while those in pots placed in cold frames do not require nearly so much attention in this respect. When the plants are fairly established in cold frames they do not require much water at present. If they are looked over about once a week, and those plants that require water are carefully attended to without spilling any or wetting the leaves, they are not likely to be injured by the disease called spot, which is usually engendered by too much moisture in the frames during the shortest days of the year. There are some sorts both of Carnations and Picotees that are seldom or never attacked by spot, while others seldom escape that disease if the surrounding circumstances are favourable to its attacks. I would not say that we have never had any spot on our own plants, but I cannot recollect an instance of its appearance, and believe that the plants can be kept clear of it by free ventilation and the maintenance of as dry an atmosphere as possible at all times. I believe that Mr. Dowell's plants, although in a damp smoky atmosphere, are practically suffering from its attacks.

Dahlias.—Where the roots of these have been stored away, it is necessary to look over them occasionally to see that the crowns of the tubers are not injured by damp, caused by the stems decaying. If this has happened, the decaying portion must be carefully removed, and the root thus affected should be taken out and placed in a light airy position to dry. All that is required is to keep the tubers in a comparatively dry place, where frost cannot penetrate.

Phloxes and similar plants in pots are now comparatively at rest in cold frames. It is best to plunge the pots in some rather dry material, such as fresh Cocoa-nut fibre refuse which answers as well as anything for the purpose. Plenty of air should be admitted, removing the lights when it does not rain, the same as in the case of Auriculas.

Tulips.—It was stated two weeks ago that we were fortunate in getting the bulbs of these planted out when the ground was in good condition, and also the loam that was placed over the surface of the beds for the reception of the bulbs. The question now is, what is the best treatment during winter? and this was also a question that agitated the minds of growers many years ago. One grower stated that he never covered his beds to protect them from rain, and another equally successful cultivator was careful to protect his beds from all the rain that fell. I think, however, that the first-named grower was right in principle, but, at the same time, I would recommend that, where appliances are at hand, the beds should be covered from excessive rainfall.

Cold Frames.—It is well known that where very choice collections of herbaceous plants are grown it is desirable to winter a portion of them in cold frames. The plants ought to be established in pots before the winter, and then it is desirable to plunge them in some light material. We devote a frame or a portion of one to choice species of *Primula*. In the same frame are also *IXIAS*, *ANTHERICUM*, *LILIASTRUM*, *MECONOPSIS*, *TRILLIUMS*, and, indeed, any plants the whole stock of which it is not desirable to risk in the open garden. These plants will not take care of themselves, nor do they require much attention. All that is needed is to look over the pots about once a week, and to water such as require it. The frames ought also to be freely ventilated.—J. DOUGLAS.

Indoor Fruit.

Vines.—As the season has been of such an exceptional sunless character, probably all Vines, even those that appear well ripened, and which have had a tolerably long season of rest, should not be started in any case as early as usual. It will be advisable to excite growth very slowly, and particularly so if the weather continues as severe as it now is. Adherence to fixed temperatures at certain stages of forcing is founded on a most illogical basis, as temperatures should always be subject to the fluctuations of those outside. Granted, that good fruit can be had by disregarding this rule, and that sometimes one is compelled to force against time; still, that does not justify adherence to fixtures, for, in the long run, the Vines

must suffer by such unnatural treatment, and this is proved by the fact that a large number of early forced Vines are yearly reported to have failed from no apparent cause; but which I believe to have been induced by express speed as regards forcing. It therefore becomes a question as to whether, in order to have the fruit ripe two or three weeks earlier, it is worth while to sacrifice the permanent well-being of the Vines; by the exercise of but a moment's thought, a negative reply will be given by all. Early houses that have outside borders will need protection, consisting of a covering of dry Fern or leaves in sufficient bulk to exclude frost, and sashes or shutters to throw off snow and rain. The Vines in succession and midseason houses will now all be ready to prune, and the sooner this is done the sooner will they go to rest. If they have been infested with insects, remove from the stems the loose bark only, and then paint or wash them over with a strong solution of Gishurst or soft soap and sulphur. The removal of the outer bark of the Vine is only recommended in order that the insects may be the more easily reached by the wash; where insects have not been troublesome, by all means leave the bark intact, for its removal, to say the least, is most unnatural, and must in some degree prove injurious. Late houses still require careful management in order to keep the Grapes in good condition; besides keeping the atmosphere as dry as possible—not arid—it is necessary to keep the temperature from ever falling so low as that outside, which on some mild days might be the case if not closely watched.

Figs.—In the culture of Figs there are two conditions essential to securing the best returns, the first is restricted root space, and the second is liberal manuring; the first ensures fruitfulness, and the second is necessary to its more perfect development; hence arise the generally satisfactory results that are obtained by growing Figs in pots, a plan that cannot be superseded for early work, but for general and late crops much more and finer fruit can be had by planting out. Of course, the size of borders must to some extent be ruled by the space there is for the spread of the trees, but, as a general rule, 2 ft. in depth and 6 ft. in width will be found to be ample. Provision for surplus water to readily pass away should be made by the concrete or paved bottom being made to slope to the drain in front. The soil in which Figs revel is a chalky loam, to which may advantageously be added charcoal and a small proportion of $\frac{1}{2}$ -in. bones; it should be made firm, for in a loose, spongy soil the trees are apt to grow too robustly. When once the borders have become full of roots the annual removal of the top soil will be necessary, for the purpose of adding fresh feeding material, and the disturbance which the roots thus get gives a salutary check to any disposition that the trees may manifest towards too vigorous a growth. Now is the time to apply such top-dressings, and also to place a portion of the trees in pots in gentle warmth. Bottom-heat is not necessary, but time will be gained if this can be afforded by plunging the pots in Oak leaves, in sufficient bulk to engender a heat of 65°. The leaves will give off sufficient moisture, therefore the plants will not need syringing, and for the present fire-heat will only be required when the temperature is likely to fall below 45°.

Peaches and Nectarines.—The thermometer on Dec. 1 registered 22°, or 10° of frost, with every appearance of a continuance; therefore, where forcing has commenced it will be necessary to guard against the application of too much fire-heat; better allow the temperature to sink to the freezing point than risk bud shedding through too much artificial warmth. Under present conditions, as to weather, 45° should never be exceeded; syringing overhead should also be discontinued, and instead the borders, walls, and floors should be sprinkled morning and night. Succession and late houses should also be kept closed in frosty weather, not that the trees are not hardy enough to bear a few degrees of frost without real injury, but because it is only reasonable to suppose that trees which have been subjected for some years to indoor culture might suffer if too much exposed. Finish pruning, cleaning, and tying, and afterwards remove all the old mulching and inert top soil, and replace them with good maiden loam, wood ashes, and bone dust.

Strawberries.—To have ripe fruit early in March, which is quite as soon as the fruit is good, a number of plants should now be started. Where there is no house specially devoted to their culture, one of the best positions for this early batch is a pit filled with Oak leaves, on which the plants should be set (not plunged) closely together; the warmth and moisture given off from the leaves soon causes new root action and expansion of the crowns. Caution is requisite that roots do not protrude and get established in the leaves, as, before this takes place, they should be drafted on to shelves in Peach-houses, Vineries, &c., and others put in their places. Whilst in this position they may require water about twice a week, but no syringing will be requisite, the moisture from the leaves being ample. A little ventilation will be necessary in all weathers, but when mild give air liberally. We always select 200 of the finest plants for the first introduction; half the number would be abundant, could we depend on all of them setting and swelling off their fruit well, but

at this early season it is always advisable to allow a wide margin for failures; therefore start plenty, and keep selecting the best plants, the weakest ones will do good service at the end of the season.—W. W.

Kitchen Garden.

Winter has set in early, and that too with unusual severity, therefore the protection of the various vegetable crops and saladings becomes an absolute necessity, the more so because the growth is so flaccid and watery—a circumstance which, as a matter of course, renders the plants the more susceptible of injury from frost. In districts where the common Bracken is plentiful, protection becomes a very easy matter, as there is no better material for covering Celery, Cauliflowers, and early Broccoli; the lightest sprinkling of it over the plants wards off many degrees of frost, and what is of great consideration in some gardens it does not present that untidy appearance that stable litter does, which is the next best protecting material. All heads of Broccoli or Cauliflowers that are anything like fully grown would be best lifted entirely and taken under cover. They keep good for weeks either heeled in or suspended head downwards in any cool shed from which frost can be excluded. Lettuces and Endive may also be protected with Bracken, but those that are required for winter salads ought always to have the protection of frames. Cauliflower and even Cabbage plants will be the better to have protection in severe weather. Parsley is best protected with mats resting on hooped sticks, or Pea-sticks laid over the bed. Of course all such protection should only be employed when the weather is really severe, and should at once be removed when it has become more favourable. After such hard weather it is also necessary to go over plots of Brussels Sprouts, Cabbages, Savoys, and Kales, and pick off all the decayed leaves, which not only smell disagreeably, but hinder the admission of air, which is most essential to keep such green crops in a sturdy condition. When the weather renders it impracticable to work on the ground, compost and manure heaps may be turned over, leaves and stable litter got together for making hotbeds for forcing purposes, and drains opened, ditches cleared, hedges clipped, and advantage should always be taken of dry, frosty weather to do all heavy wheeling or carting, for such work is then not only the more easily and expeditiously done, but there is no after repairing of walks required, as is the case when the traffic takes place under less favourable conditions, and thus "labour saved is labour gained." In the forcing department increased vigilance will now be requisite to keep up supplies. With proper appliances, as regards heated forcing pits and frames, this is an easy matter, but in the majority of gardens these are lacking; hence a certain amount of scheming and contriving as to how and where to grow the various crops is necessary. Rhubarb gives least trouble when the roots are lifted and placed in a Mushroom house, but the want of such a place need be no drawback, as it will do in any shed, cellar, or outhouse, only, of course, the warmer the situation the sooner it is ready; in cool places time may be gained by always watering with warm water at about a temperature of 90°. It may also be forced in the open ground by placing over the crowns, pots, tubs, &c., and using leaves only as a heating medium, as the addition of litter renders the heat too violent. Seakale is amenable to exactly the same modes of forcing as Rhubarb, except that extra care is necessary to exclude light and air to blanch it well. Forcing pits that are specially constructed and heated with hot-water pipes are, of course, the best in which to grow Asparagus; but a bed made up of leaves and a small proportion of stable litter, with frames placed on it, or a similar bed made up on the floor of a Vinery that is being forced, serves the purpose equally well. A bottom-heat of 75° should never be exceeded, and a top or surface heat ranging from 45° to 55°. For the forcing of French Beans—even when there are pits specially constructed in which to grow them—there is no better plan than having them in pots, as they can then be moved at will, and the crop advanced or retarded as may be required, and a constant succession is far more easily maintained by making a sowing fortnightly in quantity according to demand. One important item in their culture is that they are moisture-loving, and should never suffer from want of water either at the root or in the atmosphere. Carrots and Radishes force well when sown on a bed of sufficient massiveness to produce a bottom-heat of 65°; glass coverings are, of course, indispensable, but when the weather is mild the fullest exposure is necessary. If the two crops are sown in alternate lines 6 in. asunder, the Radishes will come off before they are in any way detrimental to the Carrots. Herbs are required in such small quantities only that they should always be grown in pots or boxes in any convenient place, and the same remark applies to Mustard and Cress.—W. W.

Extracts from my Diary.—December 8 to 13.

FLOWERS.—Looking over bedding plants and removing decayed leaves and weeds. Placing in gentle heat a few plants of *Diclytra spectabilis*, Lily of the Valley, and *Prunus sinensis*. Potting a few

more herbaceous Calceolarias in 3-in. pots. Potting bulbs of *Ranunculus* and *Anemones*. Re-arranging greenhouses. Tying up and staking *Mignonette*; also *Eucharis amazonica*.

FRUIT.—Pruning Trebbiano Vines, and scrubbing paint with soft soap to cleanse and kill insects that may have accumulated in crevices. Looking over Apples and Pears in fruit room, and picking out all decayed fruits. Giving Raspberries a good top-dressing of rough manure. Looking over Strawberries plunged in leaves, and picking off all decayed foliage. Tying in young shoots of Vines trained on wires for table decoration.

VEGETABLES.—Covering up a piece of Seakale and Rhubarb with manure and leaves. Spawning Mushroom bed outside and turning manure for more beds. Tying and stopping winter Cucumbers. Potting a few more French Beans, and getting in next batch of Rhubarb for forcing. Manuring and trenching ground for Potatoes, and shifting those growing in pots to a house in which they will have more light. Getting up a few clumps of Mint and Tarragon for forcing. Sprinkling a little burnt ashes and lime on Pea border as a preventive of slugs. Placing pots over Seakale ready for forcing; also covering up Endive and Lettuces to blanch, and placing a few more roots of Witloof in Mushroom house for salad. Cutting all Cucumbers ready for use, and placing them in troughs to keep. Cutting Veitch's Self-protecting Broccoli, many of which are still producing good useful heads.—R. G., *Burghley*.

TREES, SHRUBS, AND WOODLANDS.

HOW TO PLANT A SHRUB GROUP.

LET me depict to you, as nearly as I can, what I find to be the usual conception of a well-planted shrub group; I mean a shrub group properly planted according to the standard of most gardeners and lawn planters. It consists simply of an oval or circle of spaded earth, filled to repletion with shrubs planted 2 ft. or 3 ft. apart. Cultivation and mass planting are evidently here kept in view—laudable objects, certainly, in their way—but how about the arrangement of colour and form in foliage and flower? What evidence is shown in such cases of knowledge and adaptation to the various seasons for blooming peculiar to species and varieties? I fear both knowledge and taste here fail lawn planters and gardeners in very many cases. Must we draw the inference that lawn planting skill is at a low ebb among those who should know it best? If not, how otherwise can we account for the fact that knowledge and taste are so conspicuous by their absence in the construction of most shrub groups? One might fancy that the bedding-out system applied to ribbon gardening had furnished models for planting many of our deciduous shrub groups. But no, I would not so insult bedding out, oftentimes excellently done, by making it responsible for such slovenly, unsatisfactory work. Here you have generally a fair study of colour and form, and time of blooming. In deciduous shrub groups, on the other hand, small plants even are frequently huddled where large plants ought to be, and *vice versa*. Perhaps you will say this is mere captious fault finding. I can do no more, then, in defence of these assertions than tell you briefly what I consider a well-planted shrub group. Assuming, first, a knowledge of the seasons of blooming and the colours and forms of shrubs, I would look at any hill-side group of wild plants and get what hints I could from their arrangement. In short, I would ordinarily plant my shrubs 4 ft. apart—in rare cases 3 ft.—dig only a circle of about 1 ft. in diameter around the plant, and fertilise liberally on the top of the ground. Frequent spading for cultivation is as necessary here as ever, and is generally neglected. The Grass must, of course, be kept neatly trimmed among the plants, and though the use of a sickle be found necessary at times, the improved and cleanly appearance thereby attained will fully repay all trouble.

And now a word as to arrangement. It is commonly the habit, where any defined system of arrangement is attempted, to place the large plants in the centre and the low ones on the

outer edges. In a general way this is correct, if the work be not executed in a formal manner. Such grouping is, however, not strictly correct from the standpoint of natural planting. Here and there through the mass, even to the extreme end, taller plants, such as Tamarisks, &c., should be so disposed as to give an irregular wavy sky line. No sharp transitions in height should be allowed; that is, a shrub adjoining this specially tall one should not be sufficiently small to make a sharp contrast. Again, plenty of shrubs of the same variety may be massed in the centre of the group, but on the outskirts more numerous varieties may be disposed. This applies, however, only to groups of considerable size. Smaller groups may be planted with shrubs, each of a different variety. Trees of moderate size may be planted in the group instead of the larger shrubs, which ordinarily should form the high points of the sky line. Large shrubs or low trees dotted singly near points of outer curves also increase the natural effect. Due regard should be given to scattering different colours about the mass, so that a number of red flowers, for instance, may not be crowded in one spot, and none at all be seen elsewhere. The same management should apply to the arrangement of the plants which bloom at different seasons of the spring and summer. I doubt not that many will wonder that so much study should be given to a group of shrubs. But it would not be thought much if it were once understood, and the effect is really greatly superior to the common style of nondescript arrangement. In conclusion, I should say what has been already implied, that culture is obtained as well in this way as in any other. It is also in place to call attention here to the yearly necessity of pruning shrubs at the special season when provision is best made for flowers during the coming year.

S. PARSONS, in *Country Gentleman*.

AUTUMN TINTS.

WHENCE come these? Hitherto we have persuaded ourselves that warm summers, warm dry autumns, and well-ripened wood were quite indispensable to the production of anything like gorgeous autumn leaf coloration. This season has proven quite the contrary, for we have had no summer in the ordinary sense of the word—nothing but wet and cold—and yet I never remember to have seen such fall and rich autumn tints before. The common trees—Beech for instance—have been remarkably fine. Within view of where I write there are some mountain slopes fairly wooded with Beech freely intermixed with other trees, and these slopes alone produced remarkable features, for the trees did not appear to come to maturity altogether. On the contrary, one here might be seen just assuming a yellow hue, there another merging into orange, and again one exchanging the orange for brown, and such browns, full, ripe, brimful of colour; and, moreover, the period during which these changes were produced was of much longer duration than usual. I think that instead of searching for the source of coloration in warm summers and autumns we must rather look for it in a copious supply of moisture, and just sufficient warmth to enable hardy trees to make their growth. Thus circumstanced, they store up a larger than ordinary supply of juices, which, when the proper time comes, gradually but surely undergo that process which changes green to yellow, yellow to red or brown, and so on. Be that as it may, however, the fact remains, and the keen observer has been enabled to make copious notes for future use.

Populus nivea was very charming this season; some of its leaves were bright yellow, others green, and others again showed the silvery under-surfaces. I noticed in one place, close to a piece of ornamental water, a specimen of the Weeping Poplar; this was very fine, the leaves changed first to a yellowish orange, and then to red and full crimson, and they remained so for a long time. The American Oaks have been as bright as could be, showing that for them, at least, we do not require an American sun. The Sumachs have been truly gorgeous, clothed, as they have been, in crimson. The Liquidambars, so highly spoken of as conspicuous in American woods, never become here more than purple, and this year they formed no exception, showing that in their case they want something that we in this country have not got. On the other hand, *Parrotia persica*, in all positions—in full exposure to light, and also in half-shady places amongst other plants—ripened into the most beautiful

tints of orange, pink, crimson, &c.; perhaps the most remarkable of all, however, was a bush of *Stuartia grandiflora*; this, though in a half-shady position, assumed the richest possible hues of orange, red, and ruby-crimson, with a sort of second colour shining through them. The various Maples have been splendid; *Acer colchicum rubrum* was worth going a journey to see; the growing points of this tree are always of a vinous-purple, and this remained until the last, in fact, until all the lower leaves had become bright yellow, thus representing a mass of gold, with purple points thrust up through it here and there. *A. ginnala* assumed tints of crimson, almost vieing with those of the Cardinal-flower. *Rhamnus latifolia* gradually changed from green to yellow, and this went on until the whole bush was rich golden yellow, highly suggestive of what huge bushes of yellow *Calceolarias* would be, and thus they have remained for a long time, and appear likely to continue for some time yet.

What to me has seemed remarkable is that *Cotoneaster Simonsii*, after producing a rich crop of berries (which, by the way, were very late in ripening), almost rendered them invisible by the rich colours assumed by the leaves; in fact, it was quite a struggle between the foliage and berries as to which should be the most conspicuous, and so the effect was quite dazzling. The Ashes also looked quite cheerful in their sombre yellow, beyond which they did not get, and now the Elms—always late—are striving to emulate the Beeches, since departed. Many evergreens have also caught the infection; the Berberries especially are assuming tints quite unusual in their case, the points of *B. Aquifolium* being rich crimson, and *B. Darwini* also changing from green to yellow and crimson. Fruit trees again, especially Pears, have been very fine. Altogether, the tree lover cannot fail to have been highly gratified, and moreover much instructed, by the rich treat which the autumn tints this year have afforded him.

Newry.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Large Wellingtonia gigantea.—An uncommonly tall and handsome specimen of this tree is growing in the pleasure grounds at Ponthill Gifford, near Salisbury. It measures 54 ft. 9 in. in height, and girths at 5 ft. above the ground 7 ft. 5 in. This is the tallest *Wellingtonia* by about 2 ft. that I have ever seen; I question whether there is another specimen so tall in England; the girth of stem, too, is also remarkably great, considering the few years it has been in this country. Twenty-six years ago, I believe, Mr. Lobb first sent seeds of this Conifer home, and, probably, this specimen was not planted in its present situation for at least three or four years after, thus showing how rapidly it has grown, averaging nearly $2\frac{1}{2}$ ft. every year since it was planted. Notwithstanding, however, the fast-growing propensity of the *Wellingtonia* I have reason to doubt that it will ever become valuable as a timber tree; some planks of it in my possession, 1 ft. broad and 2 in. thick, are comparatively speaking as light as cork, and, I fear, would not resist the alternations of wet and dry weather, if used for outdoor work, many seasons without undergoing rapid decay.—GEORGE BERRY.

Pyrus Malus floribunda.—It often occurs that we get notices of the good things when they are in flower, which is, of course, at a season when it is too late to plant, and I would therefore bring the merits of this most beautiful deciduous shrub before the readers of *THE GARDEN* now, that they may take advantage of it to obtain plants, and get them planted as soon as the sharp weather has left us. In growth and habit this *Pyrus* resembles the Quince, having long pendulous twiggy shoots that emit clusters of blossoms from every bud like those of the Cherry in size and form, but instead of being pale as they are, have the lovely rosy tints of Apple blooms, so that a bush or tree of it is a strikingly ornamental object in the spring of the year, and one well suited for any lawn or conspicuous position among evergreens, which help to show it up to advantage. To get it to flower freely it should have an open sunny situation, that the wood may become well ripened, and if sheltered from the north winds all the better, as its beauty is apt to get marred and cut short if the branches are blown to and fro by the cutting breezes that set in from that quarter. Japan has yielded us many hardy floral treasures, and the *Pyrus Malus floribunda* is one of the best, which nurserymen have not been slow to perceive, and anticipating a large demand for it have worked up a good stock. It is more than likely that it will be valuable for foreign, and if it will bear that treatment, neat headed standards would be quite a feature in any conservatory.—S. D.

Pittosporum Mayi.—A short time since I saw a most beautiful plant of this *Pittosporum* growing in the grounds at Pridcaux Place, Padstow, on the north coast of Cornwall. It was 18 ft. high, and 13 ft. through. Is this size anything unusual? or does any of your correspondents know of larger or better plants? This one seems

to have withstood the last severe winter without the least injury, whilst at Trelissick, on the south coast, several good plants of it, and also of *P. undulatum*, were killed; and at Porthgwithden, only about a mile distant, several fine plants were not in the least injured.—SANGUINEA.

Thujopsis borealis variegata.—This is a very well-marked and beautiful variety of *Conifer*, much superior to the plants of that kind that have been seen about. I speak of the Bagshot variety, which is in Mr. John Waterer's collection.—H. V.

Tropical Fig Trees.—The accompanying illustration shows well the extraordinary and vigorous character of some species of trees in the Tropics. At home with us tree growth is steady and limited, so to speak; the stems of trees are often formed with some kind of regularity of growth and rotundity. The

Grotesque shapes of a species of *Ficus*.

Fig trees of the South American river valleys, which pile buttress against buttress, and build their stems, have a wild luxuriance and superabundance of vigour of which we here know nothing. I bought a print showing a great Fig tree near Bombay the other day which really embraced in the spread of its many branches bowers, or rather temples, beneath which numbers of people could sit and amuse themselves.—H.

A Venerable Yew Tree.—“A Subscriber” invites attention to a remarkable tree, “believed by many to be the oldest living tree in the kingdom,” now in danger of destruction by the axe. It is in the churchyard of Buckland, near Dover, and is known as the Buckland Yew. It appears the church has grown too small for the needs of the parish, and it is proposed to extend it westward, in which case the Yew tree must be cleared away. Our correspondent implores that this may not be done. We cannot offer any opinion on the subject, being unacquainted with the details of the case. But we can make a general remark to this effect—that, as a rule, to which the exceptions are exceedingly few, the enlargement of an old church is a grave mistake. The process spoils the structure, and does not result in a comfortable arrangement for the worshippers. The prudent course to pursue is to build another church and

preserve the old one as a landmark and record of the past. We did that at Steke Newington, and our dear old parish church, with its tiny spire, remains intact and hugged by the trees that have loved it long.—*Gardeners' Magazine*.

THE FRUIT GARDEN.

PEACH CROPPING AND TRAINING.

MR. COWBURN (p. 458) made certain assertions regarding the disadvantages of the extension system of training, and being asked by me for proof of his statements, he answers that he was taught “in a school evidently superior to that in which the extension system is advocated,” which may be so, but he fails to produce evidence of the fact. He complains also that “it is unfair for me at this season of the year to doubt the number of fruits which his trees have borne.” May I ask, did he give your readers an opportunity of verifying his statements when he sent examples to THE GARDEN office on August 16, which were “stated to be the remnant of a crop” that he had been gathering for some weeks previously? And now a word regarding the quantity of fruit gathered. I fancy I know pretty well what a Peach tree can do under good culture, but Mr. Cowburn's statements do surprise me, and really require looking into. We are now told that his tree bore “ten good 7-oz. fruit” to the square foot, which is asking us to believe that his Peach tree, 22 ft. square, (484 square feet), bore considerably more than a quarter of a stone of fruit to the square foot, or only two hundredweight less than one ton on the whole—a weight probably greatly exceeding that of the tree itself, roots and branches. Whether such a thing is possible or not, even once in a way, I leave your readers to judge. Mr. Cowburn states that he has obtained continuously such crops regularly for years. It is not the quantity I doubt; there is nothing surprising in that, but the size and quality; and I think it probable that the fruit generally was more like small marbles than anything else, and proportionately poor otherwise, though 7-oz. fruit might have been produced here and there where the crop was thin. When Mr. Cowburn has such another crop to show I would gladly, if well, make a journey to see it. I may remark that the sample of Nectarines sent by Mr. Cowburn to THE GARDEN Office in August simply showed that he had not thinned his crop at all. “Within a space of 6 in.” there were five Nectarine bears, and judging from the space and the way in which the Nectarine bears, these must have been about the size of Gooseberries. J. S. W.

[No; they were good-sized Nectarines fit for any table.]

GIVING MANURE TO FRUIT TREES.

THERE are certain principles easy of recognition which should always govern the application of solid manures to fruit trees. So long as a tree is making a fair average annual growth, according to the variety—and there is much variation in the vigour of different kinds—rich solid manures would be hurtful. This need not, of course, prevent help being given at times when urgently required, either in the shape of a sprinkling of guano or other artificial manure, to be afterwards watered in, or it may be given with good effect in a liquid state. The best time to give quick-acting stimulants is in summer, when the trees are carrying a good crop of fruit and seem to require help speedily. The best time for using solid manures is doubtless in autumn; they should be applied just beneath the surface, but not necessarily in immediate contact with the roots. An inch or two of the surface soil may be removed, the manure spread over, and the soil scattered over again. In the case of very old, exhausted trees, whose roots are for the most part deep in the earth, the manure may be buried deeper, nearer to them, to be the more easily available, and it should be given in greater quantities. Many of the scrubby old Apple and Pear trees that seem past redemption might be brought back to health and usefulness if treated in the manner suggested. The wonder is that it seldom occurs to people to help them in this way. Year after year, what fruit the trees bear is gathered and taken away; the leaves, too, fall and are blown by the wind to the nearest dyke, and no part of the load the trees have carried is given back to them again to help to support them. Small wonder is it then that, after a certain period, their vigour fails. In good, fertile land the struggle is, of course, a protracted one; but even in the best land, after the first flush of youth is over, trees that are bearing heavy crops of fruit need support, and when they cease to make a reasonable growth annually it is time for re-invigorating measures to be taken in hand, and there is no plan so good as the application of rich top-dressings. The way in which the roots of trees seem to find their food, even if placed at a distance from them, is very remarkable; and as it is certain they have this power of discovery, by

placing their food near the surface they are brought within the influence of air and sunshine.
E. HOBDAV.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Late Black Hamburg Grapes.—Allow me to say that the words attributed to me by Mr. Cowburn (p. 496) on this subject are not to be found in my remarks of the previous week. I did not say that Vines started late would mature their fruit "by the beginning of October," or that they could be retarded at starting time "till the latter part of May, or even later." "About the beginning of October" and "till May or later" were my words; and I still say—and am prepared to prove, if necessary—that Black Hamburg Grapes can be ripened in the period I have stated. We were cutting good and well ripened and coloured Black Hamburgs from Vines this season, the first week in October, that had not burst a single bud by the end of April, and we have been cutting from that house until now, and the fruit looked as if it would keep well for another six weeks, as it has done before in the same Vinery and on the same Vines. I have started Vines in November, and cut from them the first week in April; and hundreds of other gardeners have done the same. But Black Hamburgs have been ripened in even less time than this. Mr. Thomson, in his book on the Vine, states that he started a Vinery on the 1st of September and cut the first dish of Grapes from it on the 1st of January. After this, I think your correspondent's "six months, more or less," during which he says the Black Hamburg requires to ripen its fruit may be dismissed from consideration.—J. S. W.

Mistletoe Growing on the Plum.—In the Trinity College Botanic Gardens is to be found, according to the *Gardener's Record*, excellent examples of this curious parasite—so rare in Ireland—growing on a variety of Plum as freely as could possibly be desired. The plants evidently appear quite at home, being in the most robust health and showing an abundance of berries. We are not exactly sure how long it is since they were first placed in their present position, but we should say it cannot be less than ten to twelve years.

Classification of Grapes.—I doubt if that attempted classification of Grapes (p. 423) will meet "a long-felt want," first, because such a want as is indicated has not been felt, and secondly because the said "classification" is too complicated and artificial—no less than sixteen classes and sub-divisions! I do not suppose that it is intended to serve any botanical end, and it will not be popular, for the necessities of culture have compelled us to divide Grapes into three classes, like Potatoes, viz., early, second, and late, and these again into black, red, and white, an arrangement that meets all our needs. If it were desirable to class varieties by their flavour, Muscat and Sweet would describe them all; but to attempt to distinguish between "Sweet" and "Vinous" is next to impossible, and the list is a failure in this respect, for, so far as I understand the somewhat vague term "Vinous," it applies just as well to varieties in the Sweetwater class as to those in the class under that name.—C.

Peach Training at Wilton.—I noticed some remarkable Peach houses at Wilton the other day, new and very well built. The trees, instead of being trained under the roof as usual, are trained on trellises, which form walls across the house, so to say, only leaving the passage free. The houses, being very light from being glazed with large glass windows, these trees enjoy full light from top to bottom, while at the same time the light reaches the back wall to such an extent as to fully perfect the fruit and wood on it. The Peach trees had only been planted a year, yet they had made a very remarkable growth, and were thoroughly ripened. Mr. Challis has the fullest confidence in the plan, and has carried it out thoroughly well.—V.

Doyenné Boussoch.—We gathered this fine Pear at the end of October. It is now (Dec. 1) just becoming ripe, having been lately removed to a warm room. There is no trace of decay at the core, as often happens with this variety if kept a few days only beyond its season for ripening; but, although juicy and refreshing, it has neither the flavour nor the texture peculiar to this Pear in favourable seasons. A few of the forwardest, got earlier, were ready for eating by the first week in November.—B. S., *Rutland*.

Slugs.—The severity of last winter undoubtedly destroyed many of the birds which usually prove the farmers' friends. Owing to this, and the wet summer, great havoc is even now being made by slugs in many parts of the county of Kent. I have lost already one field of early-sown Rye (about eight acres), and others are considerably thinned. The late-sown Trifolium is also eaten off, and it is to be feared that the Wheat crops upon Clover lays will suffer.—A. B.

AN EDIBLE-FRUITED YUCCA.

(Y. BACCATA.)

THE annexed engraving represents a very distinct Yucca which was introduced into Europe a few years ago from New Mexico and adjoining localities. As may be observed it has a remarkably rigid habit, and has a short thick trunk. The leaves are of a light-green colour, and are erect, sword-shaped, pointed, deeply channelled, and the edges have numerous shaving-like appendages. The flowers are said to be showy, bell-shaped, white, and deliciously fragrant. Its most remarkable peculiarity, however, is the fleshy fruits, the berry-like character of which has suggested its specific name. The fruits are dark purple in colour, from 3 in. to 5 in. long, and are often beaked. These are represented in the woodcut half their natural size. They are described as being of the shape and consistence of a ripe Banana, a name by which they are known in their native country. The taste is sweet and agreeable, and the natives are very fond of them, and gather and dry quantities of them for future use. In an uncooked state they are said to possess cathartic properties.

It belongs to the Cauliscent or stemmed section of the Filament-marginate group of the genus, the species comprising which seem to be but little known at present. As regards its hardiness in this country there are few who have had the opportunity of testing it on account of its comparative rarity, but a correspondent communicated a note to THE GARDEN about this time last year, in which it was stated that small plants of it had stood the previous two winters out-of-doors without injury. On this point, however, any information would no doubt be acceptable.
W. G.

LETTERS FROM SOUTHERN FRANCE TO A GENTLEMAN IN ENGLAND.—No. II.

NICE, Nov. 25, 1879.

MY DEAR SQUIRE,—

I am glad to have your candid retraction, and to hear that the perusal of my letter has given you "more favourable ideas concerning this climate, and a better opinion of foreign parts." Pardon me when I venture to suggest that your incredulity is hardly justified in "never believing a word you hear from a lot of old maids and namby pamby young men, who go about sketching, and come home to gush;" and permit me to express my apprehension that you are in danger of overstepping the boundaries of Christian charity when you say that you "abominate fellows who can't ride to hounds." I am acquainted, I can assure you, with a number of unmarried persons of both sexes who combine a love of the beautiful with a love of truth; and I have met with individuals, brave in the chase, who were very dull and very disreputable when they were not on horseback. At the same time I accept gratefully the compliment which you pay me when you say that my account of the sunshine, fruits, and flowers, makes you long to see that which you no longer doubt; and I must thank you in the name of all France for your gracious condescension in stating, that, if only there were decent hunting and shooting, you would be disposed to come over at once. Unhappily for this nation and for me I am unable to say that the neighbourhood of Nice is a really good hunting country. Without attaching undue importance to such minor obstacles as the total absence of foxes and hounds, I fear that the precipitous hills, the multitude of trees, whose boundless contiguity of shade would make it impossible to enjoy "a break in the open," would be fatal hindrances to the sport of sports. There are none of those pleasant pastures over which we galloped together, *nondum graduati*, in those brave days of old, when Drake hunted the Bicester country, and the stag, stretching forward free and far, went bounding over the big fields and fences in the Vale of Aylesbury. There are none of those awful, yet beloved walls, such as fluttered our hearts nigh the grove of Bradwell, when my lord Redesdale was master of "the Heythrop," and Jim Hills and Jack Goddard led the van.

As to shooting, I watched yesterday the bold Chasseur, with his gun slung over his back, saw him suddenly stop, and gaze intently, as one who spies his quarry from afar, and then, bending low and screening himself under the long reeds growing by the wayside, begin to stalk his game. He came within gunshot range, he knelt silently and slowly, he took a long deliberate aim, he fired, he started to his feet with an alacrity and vigour full of joy and hope, he rushed through the reeds into the Vines beyond, and came back erect, heroic, jubilant as a conqueror from the fight, holding in his bloody

now and then, like the *pain roti* which we have at breakfast, and which is sometimes sent toasted brown on one side, white on the other, and untouched by the fire; and at the present the sky is overcast, and a gentle rain is falling (in every clime *some* rain must fall), but the air is so mild, and the foliage so refreshed, that the garden looked this morning as our gardens look on a dull morning in early June.

This garden, and the grounds about it, are formed by alluvial deposits, brought by the rivers and mountain streams, and they are protected on the east, north, and west by the

Edible Fruited Yucca (*Y. baccata*) with fruits; the larger one: half the natural size.

hand—and regarding it proudly, as though he had just been made a baronet—a poor little linnet, which we call in Nottinghamshire a spink. So that I cannot hope to see you from these inducements, and must, in consequence, transmit to you by letter, in accordance with your request, some further particulars concerning the trees, and the flowers, and the fruits which grow *sur ce sol favorisé du ciel*.

But I must first obey my conscience, which bids me tell you that the glorious weather of which I wrote to you is not without its interruptions. For two or three days it has been so hot in the sun and so cold in the shade, that I have felt,

hills, which form a crescent round them, or, to use an illustration more congenial to your taste, an horseshoe, with the toe towards the north; so that we of the suburbs seem to live in one vast garden, or rather in a series of gardens, dotted here and there with picturesque villas, many-coloured, having their walls white, their roofs red, their *jalousies* green (Shakespeare says that jealousy is green), and so fertile that, if your temperament is sanguine and your imagination lively, you may plant the stick of an old parasol at night, and expect to see an Umbrella Pine in the morning.

Very abundant and very beautiful in the Riviera are these

Umbrella Pines; but what would you say to the *Araucaria excelsa*, the Pine of Norfolk Island (of which I remember an admired specimen about 8 ft. high in your conservatory) growing up a great tree *al fresco*? How you would delight in the Magnolias, 30 ft. in height, with their vermilion seeds gleaming among the grand foliage; the graceful Pepper Tree, with its Acacia-like leaves, and its red clustering berries, and the Acacias themselves, longiflora and many others, large as your Laburnums, and covered with their yellow flowers! How astonished you would be if I could take you into the city of Nice, and show you that, which is perhaps the fairest surprise of all, the row of Palm trees with Oleanders in alternation (the former laden with Dates), which extends, with a graceful sweep from the Promenade of the English by the sea to the Place of Massena (so named in honour of the Marquis, who was born at Nice), and ending with the noble specimen of Eucalyptus, which, though only planted fifteen years ago, has a trunk and branches such as would not be seen on our forest trees in England in less than fifty or sixty years. Son, say I will take his measure and send it you; but now, having you (mentally) in Nice, I must take you up to the Castle, and show you, as we mount the hill, the wonderful Aloes, growing anywhere and anyhow, and, though their inflorescence is over, assuring us by their giant stalks, long enough and strong enough to hold a salmon, how glorious their beauty has been. And as we reach the summit, what a panorama! Let the old man point out the house in the Rue de Smollett, in which resided the author of "Humphrey Clinker;" and let him show you the home in which Garibaldi was born; and try to sympathise with the Frenchman's pride when, looking eastward over the sea, he tells you that the speck which on a fine clear day you may discern, is Corsica, the birth-place of Napoleon!

But these surprises of loveliness are incessant. Palms, encircled by red and white Roses, and by scarlet and yellow Nasturtiums; the blue flowers of the Plumbago intermixed with the crimson blooms of the Bignonia; the exquisite *Dahlia imperialis* (truly an empress among the flowers) nearly reaching the window of a second floor; the Locust tree covered with fruit-blossoms; the Tobacco tree with its yellow tubers; all the flowers which I named in my last letter, and many others, which, as yet, I have not seen. Can we wonder that such titles as "Hotel de Paradis" should be selected by the happy innkeepers of Nice, or that the people generally should hold as an article of their creed (Nicensis) that the place of their habitation is *La Baïedes Anges*. It is no fault of theirs if some of the visitors, especially those who come here that they may gamble at Monaco, suggest very different and less refined associations.

Believe me to be

Yours ever sincerely,

S. R. H.

Horticultural Millinery.—In passing through a country village the other day, I noticed a Thorn bush in front of a cottage that had been cut and tortured into some faint resemblance of a peacock. The owner, no doubt, admired his handiwork, and it gratified his vanity to see the rustics gaping at it; but, as regards real utility, the value of his labour was *nil*, and in so far as it tends to create a morbid taste for distorted natural objects, so much harm will accrue. It may be said the man with an imitation of a peacock in front of his dwelling is only a humble imitator of the great men who have gone before him in outraging Nature by cutting and trimming Yews and other trees and shrubs into all sorts of shapes more or less grotesque. The same evil spirit that presided over the topiary work of a previous generation is still extant. It was seen a few years ago in the polychrome patterns of cut Box, and the geometrical figures filled with broken bricks, slates, and stones. It is now seen in the carpet beds, that, first started in the London parks, spread all over the country.

And doubtless, when these have passed away, the same passion for improving Nature will be developed in some other direction. But a well grown, that is, a naturally grown tree or plant, always gives pleasure; monstrosities of Nature distorted never retain their hold upon our affections long. The eye wearies of the regular lines of the cut trees or the embroidered pattern, but it is never tired of resting upon the naturally irregular outline of the Oak, or the Cedar, or any other tree or plant where the hand of man has been restrained from doing more than regulating or aiding natural development.—E. HOBDAV.

GARDEN DESTROYERS.

THE GAMMA MOTH.

(*PLUSIA GAMMA*.)

THERE are several insects which occasionally appear for one season in very great profusion, and then perhaps for a few years are comparatively seldom to be met with; among them is the gamma moth, whose appearance this year in many parts of England and the Continent in extraordinarily large numbers has excited much interest and alarm. The reason why some insects at times are so very much more abundant than at others is by no means well understood, and this year it is particularly surprising that after the severe and long-continued cold weather of last winter any insects should be unusually common; indeed, insect life generally has been far from plentiful this summer. Cold weather, however, does not have so much effect upon insects generally as many persons imagine; certain grubs have been frozen until the contents of their bodies were a mass of ice without being killed, and, on being gradually thawed, their animation has returned; but a combination of wet and cold has often had a most fatal effect upon caterpillars. It is, however, certain that the gamma moth and the painted lady butterfly have not suffered much from any adverse circumstances this year; had last winter been mild and the spring warm and genial, one could have understood any insect being commoner than usual, but such was not the case. For some reason, however, a wet season seems to be particularly favourable to this insect, for in several years when it has been more than usually abundant, the weather has been particularly wet and cold; whether under these circumstances some favourite food plant is in a condition peculiarly favourable to the health of this insect, or whether the inclement weather may have had a very fatal effect on their parasitic enemies, or what the reason is is uncertain. The gamma moth is wonderfully prolific, and it is no doubt mainly owing to its natural enemies that this insect does not attain maturity in even larger numbers; for there are two and sometimes three broods during the season, and it has been calculated that a female will lay 400 eggs; if these all lived, hatched, and duly underwent their transformations, 200 females would be the probable result, which at the same rate would lay 80,000 eggs, and produce 40,000 females, whose eggs would number sixteen millions. The injuries caused to various crops in this country by the caterpillars of this moth are usually comparatively slight, but this year much damage has been done to all kinds of vegetable produce by them; they appear to be almost omnivorous, as they have been found on nearly all culinary vegetables. They appear to be particularly partial to the leaves of Peas, Beans, Beetroot, Turnips, and Potatoes, in addition to which they are very fond of Hemp, Flax, Clover, and Grass. In ordinary years on the Continent various crops suffer much more from these caterpillars than they do in England. This year the Beetroot crop in some parts of Germany has suffered most severely; in fact, in some places the crop is almost destroyed. In Saxony and Hanover, the yield is only estimated at one third of the usual amount, and, owing to the loss of their leaves, the roots which have been saved are badly grown, and sadly deficient in saccharine matter. The *Coloqne Gazette* has published a description of a machine which has been invented for collecting these caterpillars, which consists of a series of brushes, which sweep the insects into tubes, from which they fall into a receptacle; the machine is composed of seven of these tubes and brushes, and cleans seven rows of Beet or Turnips at one time, and if drawn by a horse or ox 12 or 13 acres may be gone over in one day; at Halle 6 to 8 bushels were collected per diem by one of these machines, and on another farm in the same neighbourhood, where several machines were at work, 2½ tons were collected in one day. Large numbers of the moths have been killed by lighting fires in Clover fields and dragging a rope across the field to disturb the moths, who will, when roused, fly into the fires; but as usually only males are killed by this method (for the females are not so easily disturbed) it is not considered to be of much use. Fortunately for us in England we have not been troubled by this insect to anything like this extent; in our gardens we cannot do better than pick or shake them off the plants and kill them. We

have, fortunately, the assistance of various birds in this work, starlings and sparrows being particularly useful; parasitic Ichneumons no doubt play an important part in keeping these insects in check. The genus *Plusia* contains several species, and is classed in the family Noctuidæ. *Plusia gamma* differs somewhat in its habits from its congeners, who are seldom seen on the wing before dusk, for it flies about all day long, and in all weathers fluttering over flowers, sucking their nectar through its long proboscis, and darting quickly away when disturbed, much in the same way as a humming-bird moth does; when on the wing it is very difficult to catch, even with a butterfly net. It is a very widely distributed insect, being found generally in this country and on the Continent, the northern parts of Asia, and in North America. It has been noticed in unusual numbers in many places this summer in England, especially in the southern counties in August, and particularly about the middle of the month. Mr. George Norman in the "Entomologist Monthly Magazine" mentions having found it swarming to an extent he had never witnessed before at Pitlochry in Perthshire on the 8th of June, and for a week afterwards. On the Continent it abounded nearly all the winter in the Riviera, and was seen in great numbers early in June in the Splügen Pass flying northwards. It was very abundant in Germany, as before

and legs are dark greyish-brown; the antennæ are long and smooth, and the eyes during life very brilliant. The thorax is crested and covered with long downy hairs, and on the upper part of the body are two tufts of down. The full-grown caterpillars are about 1½ in. in length, and covered with short hairs. Their heads are greenish-brown and their bodies greenish, with six white or bluish-white, longitudinal, narrow stripes, with a yellowish band on either side below them. They may easily be distinguished from most of the caterpillars of this family by the number of their legs; this species has only six pairs, which are placed on the three first, the eighth, ninth, and last joints. Owing to this arrangement of their legs, the caterpillars when in motion much resemble the loopers or larvæ of the Geometridæ in their actions; stretching out their bodies to their full length, they hold on tightly with their three pair of front legs, and then hunching up their backs advance the after part of their bodies. The chrysalis is dark brown in colour, and has a protuberance from its breast which covers the long tongue of the insect. The eggs are somewhat hemispherical and very beautifully striated; they very much resemble an echinus or sea egg, divested of its spines, in appearance.

G. S. S.

FILMY FERN GROWING IN LONDON.

A WELL-GROWN collection of Filmy Ferns is by no means a common occurrence, especially in large towns, but, notwithstanding the adverse circumstances attending town culture, one of the most thriving and choicest collections that could possibly be desired is located at Upper Grosvenor Street, Mayfair. This collection belongs to Mr. Cooper Forster, a gentleman who has for many years been an enthusiastic admirer and successful cultivator of these charming plants. His success is all the more remarkable as there are few of the more important classes of stove and greenhouse plants of which the culture appears to be so little understood generally as that of the filmy-fronded group of Ferns. This circumstance has, no doubt, arisen from the imperfect knowledge of their native habitats, and the degree of heat, moisture, light, and other atmospheric conditions which is best suited to their requirements. A parallel case is the Orchids, and especially the so-called cool-house section, which made comparatively little progress until an approximate idea of their native habitats was obtained as a standard of imitation. Orchids, however, as a rule, differ widely from Filmy Ferns, inasmuch as the former are generally confined to certain regions, which, whether tropical or sub-tropical, can be imitated tolerably well. But this is not so with Filmy Ferns, the majority of which are so widely distributed that it would be difficult to follow any definite rule with regard to according them a certain amount of heat. A striking example of this is afforded in one of our native Filmy Ferns, *Trichomanes radicans* (the Killarney Fern). Besides being found in Ireland and Wales, it extends to South and North America, the West Indian Islands, Africa, Northern Asia, and other places. In the case of this species, it may be grown in the open air in our climate, as may be seen in the York Nurseries, where it thrives admirably in caves, or it may be grown in a stove temperature, as may be seen in the tropical Fernery at Kew, where the Madeira form of this Fern is cultivated in the same temperature as those from the hottest parts of Java, Borneo, &c. That all these apparent difficulties may be overcome there is sufficient evidence in Mr. Cooper Forster's collection, which also exemplifies the simple appliances that are necessary for cultural purposes. It should be remarked, however, that the really strictly tropical species are excluded from this collection, as they are found not to thrive satisfactorily with the cool section, which is by far the most numerous, as well as the most beautiful.

The structure in which the collection under notice is grown abuts on the dwelling house, and is about 6 ft. square, and so arranged that it can be looked into from two windows. The roof is curvilinear, and is provided with shutters with which to shade the Ferns during summer, and afford protection from severe frosts in winter. The rocky bed in which the Ferns are planted is raised 2 ft. above the outside case, and rests on a strong iron grating, beneath which is what may be termed an air trough, *i. e.*, a space for the purpose of maintaining a more equable temperature. Thorough drainage is afforded throughout the entire bed, so that there is a rapid percolation of water, a point of much importance, as stagnant water at the roots seems to be very prejudicial to the well-being of these Ferns. Over the surface of the bed are placed rugged blocks of sandstone, portions of Tree Ferns, &c., at the foot of which are planted the Ferns which delight to cling to the sides of these objects. Care is taken to induce an ascending position, as Mr. Forster has found by experience that raising the plants a little is very beneficial to them; whilst on the other hand they soon get into an unhealthy condition if planted too low, or become in any way too much encumbered with soil or other material. A compost of fibry peat, broken sandstone, and Sphagnum Moss is used for planting, and a layer of the latter

1, *Plusia gamma*; 2, Caterpillar; 3, Egg (very much magnified).

mentioned. It seems probable that many of the swarms of gamma moths which have been found on our southern coasts were not bred in this country, but I am not aware that any have been actually seen crossing the channel, though they have been found on the seashore in great numbers, and there seems no reason why, with a favourable wind, they should not have crossed from the Continent. The specific name gamma has been given to this insect on account of the resemblance the white mark on either upper wing bears to the Greek letter gamma γ . The moth makes its first appearance in May, and may be found during the summer till October. The females lay their eggs in clusters on the undersides of the leaves of various plants, the caterpillars are hatched in ten or fifteen days, and, being very voracious, increase rapidly in size. They attain their full size in about three weeks, having changed their skins four times; they then each spin a fine silken cocoon of loose texture on a leaf or stem, within which they undergo the change to the chrysalis state, and in about three weeks time appear as perfect insects; these in due course lay eggs, and the metamorphoses are again gone through. Under favourable circumstances the transformations probably take less time, and there would be a third generation. The moths are about $\frac{3}{4}$ in. long, and measure 1½ in. across the extended wings. The upper pair are dark chocolate-brown in colour, with a coppery lustre in certain lights; there is a very pale straw-coloured γ -shaped mark somewhat on the basal side of the centre of the wing. The end margins of the wings are somewhat paler, and have a dark wavy line on their inner edge, within which again are sundry lines and mottlings, which appear to vary a little in different lights. The lower wings are of a smoky brown, with a broad, dark, blackish-brown band on the outer margin. The fringe is white, with a row of dark spots. The head, thorax, body,

is strewn over the surface in order to retain moisture. Considerable care is taken with regard to watering and syringing, as some kinds require a liberal supply, both overhead and at the roots, while with others it is necessary to withhold water altogether at different seasons. The present time is the season at which they are kept the driest, though of course some require a sprinkle now and then throughout the year. A couple of frames on the "leads" at the rear of the house affords accommodation for a small supplementary collection. Whether it be from the more confined atmosphere, or from the temperature being raised by being directly above the kitchen, cannot be satisfactorily determined, but the plants thrive in the position just named remarkably well, and even better than in the larger structure.

The more striking examples in this collection consist of an excellent specimen of *Trichomanes meifolium*, which is not only one of the rarest of all Filmy Ferns, but one of the most elegant. Indeed, it is unlike the majority of the other kinds, and resembles the better known *Todea superba* more than anything else to which it can be compared. The rare *Hymenophyllum caudiculatum* forms a fine mass of fronds, and nothing can well exceed the beauty of its transparent fronds when covered with the minutest drops of golden dew. Near to this species is a thriving plant of the New Zealand *H. scabrum*, which is remarkable for the chaffy hairs that clothe its stalks. The wonderful luxuriance of that most singular of all the Filmies, *Trichomanes reniforme*, is also a sight rarely met with. The specimen measures about 15 in. across and has fronds fully 4 in. in diameter, a size exceeding that it attains in its native habitat. This, however, is not the largest size it has been grown in this collection, Mr. Forster having once had a plant with fertile fronds until destroyed with thrips. The broad pellucid kidney-shaped fronds of this lovely species contrasts strikingly with the finely cut fronded kinds.

Of the Chilian *T. exsectum* there is a superb mass, with its pendent fronds like a beautiful finely-divided green sea-weed. This could not possibly thrive better if hanging from the roofs of dripping caverns, as it is said to do in its native country. By the side of the last is the exquisite little *Hymenophyllum chilense*, which is extremely rare in cultivation. It is growing on a piece of pottery-ware, in imitation of tree branches, and by the manner in which the roots cling to the moist surfaces, it evidently meets its requirement in such a position. This kind is without doubt one of the most beautiful of the smaller-growing group. The noble *Trichomanes dilatatum* has attained remarkable growth, having wavy fronds over 1 ft. long, which are so exquisitely veined, yet so thinly transparent that even small print could easily be read through the young ones. With our beautiful little Tunbridge Fern (*Hymenophyllum Tunbridgense*) Mr. Cooper Forster is particularly successful, for it is seldom seen in a healthy condition. Here are broad masses of it which are clothed with myriads of glistening fronds. A point in its culture which is strictly observed here is not to allow it to be watered overhead, but the soil only is moistened. The twining *Trichomanes Luschathianum* and *auriculatum*, that ascend from 10 ft. to 20 ft. in height in the Brazilian forests, are here healthfully twining pieces of Tree Fern, from which they apparently derive all their needs.

The very elegant *T. trichoides* with its delicate hair-like fronds, radiant with dewdrops, forms a network with its slender rhizomes over a miniature mound, and near to it is another variety, which is considered to be either the rare *Hymenophyllum multifidum* or *H. pectinatum*, two species very similar in appearance, but coming from two widely different countries; the former from New Zealand, and the latter is a native of Chili. Another rare Chilian species is *H. fuciforme*, one of the larger growing kinds with triangular shaped fronds. Then there is the North American *Trichomanes Petersii*, a pigmy growing species, which is found near a waterfall in Alabama State; this, with the charming little *T. venosum* which clothes the trunks of Tree Ferns in New Zealand, are luxuriating finely; also the rare *Hymenophyllum polyanthos*, *H. asplenoides*, *H. nitens*, *H. sericeum*, *H. hirtellum*, *H. pulcherrimum*, *H. flexuosum*, *Trichomanes tamarisciforme*, and many others. The larger growing kinds are likewise well represented, including fine examples of *Todea pellucida*, *T. superba*, *T. Fraseri*, and its near, but rarer, neighbour *T. Wilkesiana*, all developing a profusion of their feathery fronds in almost native luxuriance. Thus it may be seen that the culture of Filmy Ferns is by no means so beset with difficulties as some people imagine, and, moreover, it further proves that an elaborate structure is not indispensable to successful treatment. It would be difficult to imagine a more charming structure for a town house, seeing that it entails such little attention, for the plants merely require an occasional sprinkling from the finest watering-pot in order to render the whole of the diversified graceful verdure a lovely mass radiant with tiny dew-drops, which glisten like polished emeralds. Even in ordinary window-boxes these delicate textured plants may be grown

very successfully, and an excellent example of it may be seen in this house, for there is a closed case containing one of the finest and healthiest masses of the Killarney Fern I ever met with. In another window case there is a mixture of various kinds such as *Todea pellucida*, the Tunbridge Fern, *Hymenophyllum demissum*, *Trichomanes venosum*, and others, while in a corresponding window was a healthy case of ordinary cool-house Ferns, amongst which the beautiful *Gleichenia rupestris* was thriving capitably.

W. G.

NOTES OF THE WEEK.

Covent Garden Market.—On account of the present severe weather the trade in fruit and vegetables has been checked considerably, for not only is the produce already in the market much injured by the frost, but on account of the slippery state of the roads through the frost the growers cannot send their produce to market. Apples from America and Canada still continue to arrive, but even in the case of these in some of the barrels there are layers of ice, the result of frozen moisture given off by the fruit.

Imported Fruits.—The first cargo—or part of a cargo—of Apples, imported direct from New York by a Newcastle fruit dealer, was delivered on Saturday last, November 29. Considerable endeavours have been made of late to establish a direct business in fruit with New York, and it will be well if dealers will content themselves with something like a reasonable profit. Good table fruit is not to be had except at famine prices—6d. per lb. for Baldwin's, and 8d. for Newtown's being in many retail shops the lowest prices. The parcel of fruit just to hand in Newcastle market consists of 328 barrels of Apples, and forty boxes of Grapes. Good Grapes of local growth are realising something like 3s. per lb. in the Sunderland and Newcastle fruit shops. The supply of Almerian Grapes appears to be fairly good, but perhaps the most plentifully imported fruits are Pomegranates, of which large quantities are being sold. Pears from the Channel Islands are realising good prices, viz., from 6d. to 8d. each for moderate-sized fruits.—TYNEDALE.

A New Seedling Lily.—Mr. Hovey, of Boston, U.S.A., has sent us a wax model of a very fine seedling Lily, which he has raised. Its general appearance is that of *L. speciosum*, but its larger size reminds us of *L. arnatum*. The colour, too, is much richer than that of the former, and the spotting more profuse. The original bulb, Mr. Hovey writes, bore two stems this year, each 5 ft. high, and produced twenty-five flowers. From this it appears that we may expect finer kinds of Lilies to result from hybridising than original species.

Macken's Cyrtanthus (C. Mackeni).—The chaste beauty of the flowers of this rare Amaryllid, from Port Natal, commends it to the notice of every one. Unlike the older and better known *C. angustifolius*, the flowers are pure white, but, like those of that species, they are trumpet-shaped, with a curved tube about 2 in. long. They are borne in a terminal cluster, numbering from four to eight on an erect stalk about 1 ft. high, and they are, moreover, deliciously fragrant. The Grass-like foliage is similar to that of other kinds. These valuable qualities, combined with its free-flowering habit, and that at a season when flowers, and especially white ones, are scarce, render it a desirable acquisition, and one that will, when it becomes more generally known, gain much favour. It will also probably become a remunerative flower for market purposes.

A New Variety of Pteris serrulata.—We have received from Mr. W. Soper, 283, Clapham Road, a finely-crested form of this Fern, surpassing all of the cristate or tasselled forms which we have hitherto seen; indeed, it is more like a finely-divided pellucid frond of some of the Seaweeds than a Fern, the fronds being much thinner in texture than usual, and of a lighter and therefore a more pleasing green tint. A large specimen of this variety would, we should think, make a very effective decorative plant.

Winter-flowering Begonias.—In a house mainly devoted to these valuable plants in the Royal Exotic Nursery, Chelsea, one named *B. insignis* is pre-eminently the kind to recommend for general utility on account of its elegant habit and great profusion with which its pretty pink flowers are produced. It is also a capital plant for cutting from. Another, named Moonlight, a smaller growing kind with white flowers, is likewise a desirable plant, as well as one called Louis Van Houtte, which has salmon-tinted blooms that are borne abundantly throughout the winter. These, and several others of the better known kinds, are capital subjects with which to enliven a house during the dull days of winter. In this nursery a fine effect is obtained by mixing with the Begonias plants of the brilliant purple-flowered *Lasiandra macrantha* and other showy subjects.

Dominy's Cattleya (*C. Dominiana*).—This lovely hybrid, which is one of the most successful results amongst the many with which its raiser is connected, may now be seen in full beauty in Messrs. Veitch & Son's nursery at Chelsea. It is a cross between the gorgeous *C. labiata*, which every Orchid lover knows, and the pretty *C. amethystina*, one of the two-leaved kinds. Its flowers are intermediate in size between those of the two parents; they are of a delicate blush-white hue and are wavy, as in *C. labiata*; the lip is of a rich amethyst tint with a pale lemon centre, and is much crisped at the margins, which renders it very handsomé. Though it was first flowered and exhibited over twenty years ago, it is still amongst the choicest and rarest of plants belonging to this handsome genus.

Eucharis candida.—This comparatively rare bulbous plant at first sight reminds one of its lovely and well-known congener, *E. amazonica*. Its flowers, however, differ from those of the latter in being somewhat smaller, the corona being longer, more deeply toothed, and having a zone of yellow instead of green at the base. The flowers are produced in succession in the same umbel-like manner as those of *E. amazonica*, but they are pendent, a circumstance which adds greatly to their distinct appearance. It was introduced a few years ago by Mr. Bull from the United States of Colombia, and a coloured illustration of it was given in *THE GARDEN* in 1876 (plate XVI.). We saw it in flower a few days ago in the T range of houses at Kew.

Oncidium dasyle.—Sir W. Marriott sends us from Down House, Blandford, a raceme of flowers of a fine variety of this comparatively rare Orchid. The flowers on the spike sent are larger than we have hitherto seen them, and the markings are more clearly defined. The jet-black boss in the centre of each bloom is very singular and much resembles the back of an insect. This *Oncidium* is a kind that thrives well in an intermediate house.

American Aloes in Ireland.—A photograph showing a fine specimen of the American Aloe in flower has been sent to us from Cabinteely, Co. Dublin, and along with it the following memorandum concerning it:—I send, our correspondent says, a photo of an Aloe americana that flowered here last year—a plant which never got any particular treatment except mats put over it every winter. I calculate that it was between fifty and sixty years old. The height of the flower-stem was 22 ft. 6 in.; number of branches thirty-six, flower-spikes 120 on each, total number of flower-pips 4320; colour light dull yellow. The flower-stem began to appear the last day of May and advanced till September. When it began to flower, as one whorl of flowers came out the lower one shed away, so that it was never out all at once. The flowers stood all the frost of last autumn, and in January I dug the plant up and put it into a shed. I have it still as a relic, but it is of course quite dead. As I saw a query in *THE GARDEN* the other day about the height of Aloes I may mention that many years ago one which flowered near this part reached a height of 35 ft., and I heard of one many years ago, somewhere in Limerick I think, that reached 45 ft. I ought to mention that some days the stem shot up nearly 1 ft., others not an inch.

Callicarpa purpurea.—There are at present several plants of this in the Botanical Gardens, Birmingham, bearing bright purple berries. They are produced in clusters at the axils of the leaves, and give the plant a very handsome appearance.—J. S. S.

Orchids at Avenue Road, Regent's Park.—The rich collection of these plants in Mr. Philbrick's garden contains even at this dull season many rare and beautiful kinds in flower. Some time ago the Cattleya house contained some fine examples of *C. labiata*, including the true variety, and soon it will be equally showy with large masses of *Lelia anceps*, which have produced several dozens of flower spikes, and amongst these the lovely and extremely rare white variety, *L. anceps alba*. The Hand-bearing *Oncidium* (*O. cheiroporum*) is well represented by a fine example bearing thirty racemes of its waxy yellow flowers, which yield a grateful fragrance. In the same house are flowering plants of *Cattleya maxima*, with its beautifully veined and crisped lip, and *Lelia marginata* and allied forms. Of the charming little gem *Sophranitis grandiflora* there will soon be some fine masses in flower. It seems to thrive admirably on cork blocks in this collection, combined with a moderately low temperature. Another house is gay with a large quantity of the fine old *Cypripedium insigne*, and its varieties *Manleyi* and *Chantini*, the latter a very fine form, even finer than *Maul's*. In a house devoted mainly to East Indian kinds all are in the most robust health, especially the lovely Moth Orchids (*Phalenopsis*) which for number, size, and vigour will favourably compare with any collection we know of. Of these there are in flower the Bornean and Javanese forms of *P. grandiflora* with long branching flower spikes and blossoms 3 in. across; also *P. amabilis*, another white flowered very fine kind. The huge specimens of *P. Schilleriana* will soon be a fine sight, as most of the plants have developed long, branching flower

spikes well set with buds. The fogs, however, which are prevalent in London at this season are very prejudicial to the culture of these Orchids, as in foggy weather the flower buds turn brown and drop off, hence a fine show of bloom cannot be ensured under such circumstances. Amongst cool house kinds the rare *Masdevallia tovarensis* is represented by several plants bearing a profusion of lovely white flowers, and some of the stems are bearing three expanded blossoms. The bright orange-scarlet *M. ignea* is also in flower, as well as the almost perpetual flowering *M. Veitchi*. Of the curious little *Restrepia tenuifera* there are several varieties differing in size and colour of their flowers. Various varieties of *Lycaste Skinneri* also enliven this house, and in another cool house are fine plants of *Odonoglossum bictoniense* in flower, and also the exquisite *O. Rossi major*, one form of which is particularly noteworthy, as the flowers are larger, and the colour brighter and more clearly defined than those of the type.

Hardiness of Todea superba.—One of the prettiest sights that we have seen for many a day was a house in the Pine-apple Nursery, Maida Vale, devoted to several hundreds of fine plants of this charming Fern, the feathery plumes of which were partially covered with hoar-frost, which, combined with the deep green verdure on the fronds, had a charming effect. The house in which they are growing is quite devoid of any means of heating the air, which on one or two nights during the past week was several degrees below the freezing point. This circumstance, in itself, affords ample proof that this species is by no means a tender plant, and therefore does not require the coddling treatment which is generally accorded it. The houseful of plants in question appeared to thrive best under cool treatment, as all the specimens which it contained have fully developed very healthy fronds, and all, without exception, possess a firm central crown of incipient fronds, which now emit short, tender roots—a sure sign of good health. The present season is not the only one during which these Ferns have been subjected to such cool treatment, for, on the contrary, the same system has been carried out for some years, and even the plants under notice passed through the last memorable winter at an unusually low temperature.

The Weather at Bedford.—During the night of Monday last, the 1st inst., and also at 8 a.m. on Tuesday morning, a self-registering Negretti and Zembra's thermometer affixed to a garden wall at 4 ft. from the ground, in the rear of a dwelling-house in Bedford, nearly a mile from the river Ouse and at a considerable rise therefrom, registered 26½° of frost, and during the following night the minimum registered was 24° of frost. These are two of the coldest successive nights I have ever remarked, and at no time during last winter did the same thermometer descend below 10°, which was registered on the morning of December 24 last. As far as I can at present ascertain the indications of injury to vegetation at the experimental garden at Girtford are not serious.—T. LAXTON, Bedford.

—At Clumber the thermometer is stated to have indicated 31° of frost on the morning of Tuesday last, and 25° on that of Wednesday.

Chinese Primulas.—Messrs. Webb & Son, of Wordsley, Stourbridge, have sent us flowers of some fine varieties of these popular winter flowers, which are not only large, and their margins finely fringed, but exhibit a great variation in tint, there being every shade from deep crimson to the purest white.

Dendrobium formosum giganteum.—This showy Orchid is now finely in bloom in Messrs. Low's nursery at Clapton. It is strikingly beautiful, well worthy of a place in the most choice collection, and the fact of its flowering at this dull period of the year adds much to its value.—J. C. B.

The Shrubby Dracæna (*D. fruticosa*).—As a rule, *Dracæna* flowers are not remarkably showy, but to this the present plant is an exception. Its waxy-white flowers are borne in erect panicles. They have recurved sepals, very similar to the small Roman Hyacinth, but lacking its rich odour. It is a continuous bloomer from October to December, and would be found very useful until the supply of winter bulbs comes in. We lately saw it in the Palm House, at Kew.

The Hailstorm Relief Fund, 1879.—The committee entrusted with the distribution of this fund have now completed their labours. A list of subscribers to the fund accompanies their report on the subject, as well as a balance-sheet, from which it appears that the total of subscriptions amounted to £1013 15s. 7d., out of which £937 14s. 3d. was distributed in relief. The committee heartily thank the subscribers of all classes who placed in their hands the means whereby they were able to mitigate much of the distress of some of their suffering brethren; the clergy and ministers of all denominations for their valuable and practical sympathy; the investigation committees for much self-denying labour; and all who in any way assisted to make the fund answer the purpose which it was intended to serve.

Salvias in Winter and Spring.—Long as *Salvias* have been in cultivation few know them as they should be known. At this season they are invaluable for warm and even for cool greenhouse decoration. *S. leucantha*, *splendens*, *pseudo-coccinea*, *cacaliifolia*, *Hoveyi* (*lanthina*), *gesneriflora*, *patens*, and *Betheli* (*involucrata*) would give a charming range of form and colour, beauty, and grace of port not readily equalled by any other genus during winter and spring.—B.

ANSWERS TO CORRESPONDENTS.

Vines.—My three years' old Black Hamburgh Vine planted in an outside border has this year made much stronger growth near the top than at the bottom. What, therefore, shall I do to improve the growth near the bottom another year?—J. W. [Suspend them in a horizontal position until the lower buds have all fairly broken, and the young shoots produced by them are somewhat in advance of those nearer the top.—W.]

Planting Asparagus.—A. B.—We should not recommend Asparagus beds to be made in the old-fashioned way. The ground to be planted should be manured and trenched now to the depth of 2 ft. or more if the soil is of good quality, but bad soil should not be brought to the top. About next March or April give a dressing of salt and fork it in, and, as soon as the Asparagus makes its appearance above ground, select good two-year-old plants and plant them in rows, 3 ft. apart each way. Open pits wide enough to enable the roots to be spread out properly, and fill the holes up with prepared compost, in which the decayed garden refuse forms a chief part, covering the roots about ½ in. deep. Where the land is good the compost may be dispensed with; but, if a quick return is desired, we should always recommend it if procurable. No Asparagus must be cut next year, but if all goes on well a few heads may be cut the year following. A light summer crop of Lettuces, Spinach, or Radishes may be taken from between the Asparagus plants the first year; afterwards the tops will meet and require all the space. Annual top-dressings and cleanly culture will be all that is required.—E. H.

Wintering *Salvia patens*.—E.—Plants of this *Salvia* should be lifted from the open ground, and having the soil well shaken off from the roots, be planted in fine dry soil in a greenhouse or in a cold frame, and be so far protected that frost shall not get to the roots, which are tuberous like those of the *Dahlia*, but less fleshy. In this way they keep better than when dried and put away in sand or on a shelf. Plants in pots should have the stems cut down to the soil, and then be placed under a greenhouse stage until March, when if brought into the light they will begin to exhibit growth, and young shoots thus produced make the best cuttings. The roots may be replanted in the open air in spring.—A. D.

Morello Cherries Not Ripening.—*Worksop.*—The falling of Morello and other Cherries is not an uncommon occurrence. The roots of the trees are probably too deep, and have perhaps penetrated an ungenial subsoil. The remedy would be to try and lift the feeding extremities, working in some light loamy soil. When the roots descend too deep they are not so active as when nearer the surface, and when increased stress is laid upon them at the stoning period failure occurs. A mulching of manure after the fruit is set would be beneficial.—E. H.

Wintering Tuberous Begonias.—*Alpha.*—Pots containing tubers of these may be plunged in ashes in any place provided they are safe from frost. The tubers should never be allowed to be dust dry. Lay the pots on their sides under the staging of a greenhouse. In the spring put them on the staging near the glass, and with a genial temperature they soon show signs of life; then turn them out of their pots; shake the soil from the roots, and repot them into pots a trifle larger than the tubers, adding fresh soil. Afterwards they may either be grown on in pots or planted out.—H.

Treatment of Tea Roses in Pots.—A. B.—Prune them now, and place them in a cold frame or greenhouse, or they may be left in the open air until about the middle of January if well protected with bracken or litter of some kind. If the plants have the appearance of being pot-bound, shift them into the next sized pots, using a compost of fibrous loam, a little leaf-mould, and thoroughly decomposed manure. If the loam is of a heavy character make a free use of leaf-mould. Tea Roses do not like a close tenacious soil.—C.

Names of Plants.—*Mona.*—1, *Aspidium angulare*; 2, *Asplenium Filix-femina* Moereri; 3, *Aspidium aculeatum grandidens*.—*G. B. L.*—*Bupleurum fruticosum*.—*H. G.*—1, *Aspidium aculeatum*; 2, *Polypodium vulgare*; 3, *Aspidium angulare proliferum*.—*N. B.*—The Asters were too much withered to name.—*R. P.*—1, *Chorozema varium*; 2, *C. ilicifolium*.—*J. E.*—*Passiflora* (next week).—*G. W.*—*Erigeron glabellum*.—*S. T.*—1, *Rivina laevis*; 2, *R. humilis*.—*Enquirer.*—1, *Cotoneaster frigida*; 2, *C. affinis*; 3, apparently *C. thymifolia*.—*G. W. S.*—1, *Erica gracilis*; 2, *E. cerinthoides*; 3, *E. mammosa*; 4, *E. hymnalis*; others next week.—*Reader.*—1, *Taxodium sempervirens*; 2, one of the numerous forms of *Cupressus Lawsoniana*; 3, *Picea nobilis*; 5, *Abies Smithi*; the others we cannot name from such scraps.—*R. D. T.*—*Adiantum decorum*; *D. M.*—Fruits of *Euonymus europaeus*.

Names of Fruits.—*Prunus.*—The Plums you send are undoubtedly Coe's Golden Drop, but the flavour is, as you observe, somewhat different than usual.—*Subscriber.*—Apples—1, Keswick Codlin; 2, Cellini; 3, Northern Greening.

Questions.

Lapageria Shoots Burying Themselves.—We have several large plants of *Lapageria*, and on examining them I find that some of the strongest shoots under the soil are travelling in a slanting direction towards the drainage, instead of coming to the surface. When the shoots in question first started, they were only 2 in. from the surface, and yet they go some 4 ft. or more, and grow fast into crevices in the stonework. There was nothing to prevent their coming to the surface. Can anyone say what is the reason of this, or suggest a remedy? Many shoots are eaten off at a depth of 6 in. from the surface by either slugs or woodlice. Do woodlice eat the young shoots of the *Lapageria*?—T. C. A.

Blue-flowered Greenhouse Plants.—What are the best really blue flowers for cultivation in a small warm greenhouse? There seems to be some scarcity of flowers of this colour especially during the summer and autumn months.—A. K., *Bastedott*.

Anacharis Alsinistrum.—Having emptied and cleared a pond of this horrible weed, I am anxious to know whether exposure to the air for a month or so will completely kill any rooted portions that remain high and dry among the flags and Rushes, or must the water also be removed? Can any of your readers help me with their experience?—A. K., *Bastedott*.

Setting Boilers. I am about to fix a 54 in. riveted saddle boiler to heat four houses. Could you kindly say what depth it should be below the lowest pipes to ensure good circulation? I am rather cramped for depth of stoke-hole.—W. S.

MARSHALL WILDER.

MARSHALL WILDER has, for a long series of years, done such good work in America in connection with pomology that we feel sure his portrait and a short account of his life (condensed from the *Rural New Yorker*) must be welcomed by many in this country. He was born September 22, 1798, at Rindge, N.H., and at the age of twenty-one his father took him into partnership, which continued until 1825, when, in search of a wider field, he moved to Boston. The firm of Wilder & Payson was at once formed, and under various modifications of firm names, Mr. Wilder has continued a merchant of Boston to the present time, honoured and successful. But trade and the acquisition of wealth were not the all-engrossing pursuits of his mind. After devoting a suitable time to business, he gave his leisure to horticulture and agriculture, and especially to pomology; he has indeed filled several large volumes with descriptions and delineations

Marshall Pinckney Wilder.

of fruits proved under his own inspection. Floriculture was also one of Mr. Wilder's favourite pursuits. His *Camellia* house is supposed to have contained the best collection in America. Two seedlings, *Camellia Wilderi* and Mrs. Abby Wilder, were named in compliment to him by the Massachusetts Horticultural Society. But it was in pomology that he was most successful and most widely known. The Pears in his orchard, consisting of 2500 trees and 800 varieties, became as noted as the *Camellias* in his conservatory.

In 1848, as president of the Massachusetts Horticultural Society, he headed a circular calling a convention of fruit growers throughout America. This resulted in the organisation of the American Pomological Society, of which he is at present the president. From the stand-point of the Massachusetts Horticultural Society he originated the American Pomological Society; then the Norfolk Agricultural Society; then the State Board of Agriculture, and the Massachusetts Agricultural College, and finally the United States Agricultural Society. His military title is the result of his interest in various militia organisations. After the death of his first wife in 1831, he sought retirement in Dorchester, where he has re-married twice, and now lives surrounded by all the influences that contribute to the charm of existence. When we look at his success in the arts of cultivation, and then turn from these more humble objects and consider those other memorials, especially the noble institutions which owe their origin and success, in a great degree, to his influence and efforts, it cannot be doubted that in the roll of the benefactors of mankind, one of the most prominent names in this age and country will be that of Marshall Pinckney Wilder.

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

LEAFLETS.

MUCH as we may grumble about our winters, from the point of view of trees and landscape beauty they are delightful. The wider views which we get when the leaves fall, the glorious contrast of leafless and evergreen trees, the gardens of Lichens on the stems, clouds of delicate spray of trees glowing into colour in the distance—these, and much more we should miss without our winters.

This fact was never brought so forcibly to my mind as last Saturday in Goodwood Park, when the glorious sun shone out and lit up hoary trunks of Oak, great spreading Cedars, and distant slopes of forest spray, with a refulgent beauty that was almost startling. The delightful contrasts between British Oak in fine groups, and evergreen Oak in groups equally fine, with Cedars of Lebanon, changed completely the character of the landscape from what is usually met with in English parks.

Cedars of Lebanon we all see and admire in pleasure gardens, but this is the first place I have ever seen where the majesty and noble variety of this tree are truly shown, scattered in groves and groups and as single specimens over a large and varied landscape. Assuredly we do not want to be told of its beauty and value for our gardens, and of its great superiority to the majority of the "fashionable" Conifers now being planted everywhere, but we do want to get some idea of its noble uses in park, forest, and hill scenery.

No pleasure-ground preparation of deep, well-selected, and gathered soil for these giants of the hills, which here compete with the sturdiness of the finest British Oak! Scant soil over chalk, and perfect exposure to the hill and sea winds is their fare. One tree is well up the hillside, perfectly exposed on every side, and beyond a picturesque leaning of the plumes in one direction shows quite as little sign of suffering as a group of the common Yew below it. Somewhat larger and more stately in the lower level part of the park, the great Cedars contrast superbly with the rock-like strength of trunk and delicate filigree branching of the naked Oak and Chestnut.

Some wise planter must have been here years ago to give us all this grouping and stateliness of tree life without torturing the sward with dots, or obscuring the delightful view of sea and hill, Oak, and Chestnut, and Lime, fine in stature and in form, being all grouped like herds of great creatures that like to keep together : and then away on the hills grove after grove of Fir and Beech, with here and there the dark plumes of the Yew, or the pale green of Box bushes grouping themselves prettily outside the masses ; fields of snow between, and standing clear out of the nearest down those round tufts of trees so characteristic of the country, and beyond at last fleecy downs, pale in the winter sky.

It is pleasant to turn from these cooler portions, and get down on the sunny side of the groves of large evergreen Oaks, which stand shoulder to shoulder with the common British Oak, as if to prove that while not shrinking a leaf before the bitter blast, they can attain almost as great stature as their summer-leaving brothers now naked. Close in groups

with polished leaves, these afford a fine effect in the landscape ; few indeed, are the trees so worthy of attention as this Oak, and nowhere is its merits better shown as in Goodwood park.

And not merely as a park or garden tree is this Evergreen Oak of Southern Europe valuable here. Nothing would give such perfect shelter to an orchard on the hills ; a village or a farm might well be protected in part with so fine an evergreen tree, which keeps the wind off better than a wall, instead of with the trees that stand naked and helpless before the gale.

Among the more remarkable trees at Goodwood are two specimens of the Cork Oak, which are singularly interesting, especially when the morning sun gives to the bossed bark a beautiful golden-brown hue. One tree is round and massive in form, but the other is broken off at one side and "weeps" on the other, making it a most picturesque object. The bark of these trees is so beautiful that no opportunity should be lost to grow the Cork Oak in districts where it does well, and there are many such.

Among all this stately life, there are one or two dead trees barkless and blanched like an old Larch high on the Alps. It is, however, quite right to keep them where they are, as they decidedly add an important element to the picture. Leaving one or two dead trees would often produce a desirable effect. Such trees may be treated in two ways. When stricken in all their strength and beauty, they are perhaps most effective when allowed to stand white, and free from climbers or Ivy. If mere stumps or not otherwise remarkable, a free-growing hardy climber like the white Clematis will soon throw a graceful veil over them.

Is it not too commonly assumed that undulation of the ground is necessary for the production of beautiful effects in landscape gardening? I think it is, and that much of the pottering and shovelling about of the earth for the sake of getting a little feeble diversity is worse than wasted. Some of the finest effects obtained at Goodwood are from trees planted on level or nearly level ground, and no other disposition of the ground could improve the scene. In another part of the park steep slopes and soft little valleys, characteristic of the chalk, produce a fine bold diversity of surface. Notwithstanding, however, some singularly happy effects, beautiful groups and wide-spreading of wood, and valley, and lawn, there is not, on the whole, any effect so stately beautiful as that on the level park.

The eccentric owner of Welbeck is dead—a man not without merit as a horticulturist, if we judge by what was done at Welbeck during his life-time. He was the owner of great estates in England and Scotland, but in his later years he became somewhat of a recluse. His father, having become impressed with the idea that there was to be a scarcity of Oak, planted a tree wherever he could, until his park at Welbeck Abbey, in Nottinghamshire, was almost a plantation when he died in 1854. His son and successor, on taking up his residence at Welbeck, proceeded to improve the estate, cutting down the superfluous timber, and laying out the park.

He constructed then one of the most perfect series of kitchen gardens in the kingdom, with one of fruit, and forcing, and orchard houses, and spent much of his time and a great part of his income in putting his seat in the most perfect order for receiving and entertaining guests in ducal style ; but, owing mainly to the state of his health, he kept no company and gave no entertainments on any occasion.

A local contemporary, in speaking of his Grace's endeavour to convert a stream through his park into a lake 6 miles long, says: "Hundreds of labourers were employed in this and other work on the estate in hand at good wages, but on one condition—no one was to speak to him or salute him. The man who touched his hat was at once discharged. The village doctor and the parson had the same orders. The tenants were informed of the duke's wishes, and if they met him they were to pass him 'as they would a tree.' Yet he was constantly about his domain, planning and superintending improvements."

Amongst his other eccentricities was that of creating a second and very important kitchen and fruit garden, and employing a separate gardener for it. This was done in consequence of some slight misunderstanding between him and the late Mr. Tillery, who had long been the gardener there, and who made a superb series of gardens at Welbeck only a few years ago.

When poor Tillery was showing any one round the place and when, on turning a corner, they saw his Grace in the distance, they retreated as antelopes might on beholding a lion. He, however, had a not unkindly way of settling differences, as witness the formation of the fine new garden, alluded to above, so as to avoid contact with the old gardener, although the latter had been at Welbeck for some forty-five years.

Many are familiar with his plan of sinking roadways in very costly tunnels underground, lighted by gas, and ventilated by glass apertures. He also built some years ago many cottages on his estate at Welbeck, but to this day they are quite bare, not even so much as a Rose branch being allowed to be fastened to their walls. He removed, too, the homes of his men so far from the place that they had to go to and from work on donkeys, a good herd of which were duly put up in the daytime in fine stables, or allowed to graze about the Abbey.

The late Duke cut down all the Larch trees on his estate at Welbeck, thinking them useless through disease, and he tried to induce his neighbours to do the same. He came to Lord Manvers, and they resolved to cut down some Larches in order to examine their condition. Twelve were cut down, and they proved to be sound. The Duke afterwards suggested that the forester, Mr. Jamieson, who did not agree with his opinions, knew that he was cutting down only sound specimens. Mr. Jamieson heard of this, and suggested that the Duke should select his own trees; he did so, and they were also found to be sound, a circumstance which probably saved the Larches at Thoresby, which are now valuable timber, one of them being, perhaps, the largest in the country.

Formal Roseries are not very pretty as a rule, and they are frequently set down so that their presence is a blot. At Thoresby a Rosery has been formed on a small island at the head of the lake, cut off from all other gardening, and the effect is excellent. It is a quiet nook in which there is a summer house. Such arrangements are better than those commonly in use.

Mr. Gumbleton tells me that a gentleman on the Continent has secured the double form of the creeping Forget-me-not (*Omphalodes verna*). I call it the double Forget-me-not, because where it does well it throws out little runners. It loves upland and moist districts, and woody or half shady places and moist soil. It is a gem for the wild garden. This will be pleasant news to lovers of hardy plants. This plant is such a favourite that even those who do not care about many double flowers will be curious to see how its blossoms

look in the double state, but I fear they cannot be so pretty as those that are single. It will be useless to apply for this for some time yet, as it is not yet increased sufficiently.

I hear that M. Froebel, of Zurich, has got hold of a pink St. John's-Wort (*Hypericum virginicum*), which will be of great interest to all lovers of hardy plants. These long-neglected plants are now being looked after in some good collections, and we shall no doubt some day have plenty of their beautiful polished golden buds about us.

Mr. Gumbleton is most enthusiastic in his description of the extraordinary beauty of the Begonias now being raised abroad, many of which he saw during his autumnal tour on the Continent. M. Lequin, of Clamart, near Paris, has a splendid series of double kinds.

I received poor A. Revière's book on the Bamboos, which had to be finished by his son—a book which is a monument of horticultural and botanic knowledge. We hear a good deal of the uses of Bamboos in other countries, and know a little of their beauty in this, in our glasshouses and in favoured gardens here and there. But the French seem to see a source of profit in this plant when grown on their southern shores and in other parts of the Mediterranean. There a great many species thrive. All that is known concerning them is mentioned in this excellent book, which also illustrates their mode of propagation and culture, which is of peculiar interest to any body inhabiting a country a little warmer and sunnier than our own. With us, however, in genial spots several kinds are known to be hardy enough for culture in the open air, and indeed to thrive there well. Probably more may be found, but in any case what we have are very valuable for our gardens.

One wishes the same could be said of some of the Eucalypti, which are now so often talked about. Whatever may be the reason of the craze for this Eucalyptus, it is the most absurd and widespread that has taken place in my time. Plants that have been thoroughly tried long ago, and which are known to be utterly useless for our climate, are planted round London and in other most unlikely places every day. To see them among the bedding plants nobody would mind, but it is odd to see intelligent beings planting them out among trees; and of course they occupy places and cause money to be spent which might be devoted to things which will do in our climate, and perhaps do for us what the Eucalyptus does for other climates, if that were necessary.

So far as I know, no better man could have obtained the Epping appointment than Mr. McKenzie, who certainly does know something about the work. The appointment is a most important one, and novel in its aim, that is, the preservation and conservation of the beauty of the Forest. It is not a question of gardening in any ordinary sense, and yet such a place might be made a noble garden by the mere development of its natural beauty.

I hear from a correspondent that the committee object much to any introduction of foreign trees, wanting a general English forest; yet, strange to say, the only bit of tree planting they have yet done is apparently to plant foreign trees. They have planted a straight avenue of Poplars—foreign kinds, of course. Planting a straight avenue of Poplars in a forest does not seem the best way to do that which by Act of Parliament they are bound to do—preserve its "natural aspect."

I have often thought that it would be a very excellent thing in a large forest like Epping to collect and plant the varieties of British trees, as, for example, every known kind of Oak and Hawthorn, as specimens, in groups, or groves, or masses, so that we might see their effect not merely as it might be in a botanic garden. What there would seem a mere variation, would, perhaps, when the trees were fully developed, have a most important value from an artist's or a planter's point of view.

I amused myself on one of those recent cold days by roasting some Sweet Potatoes in hot ashes—roots that I bought from Mr. Garcia in Covent Garden. I mean the Sweet Potato of North America, which is so good when roasted or baked. For the first time I found that these Covent Garden specimens turned out very well. The Sweet Potato is an excellent vegetable, and I should advise our American friends to send us quantities of well-ripened roots, and also tell us how to cook them. I noticed in America that, just as with our common Potato at home, there are wet and dry tubers, mainly owing to differences of soil. I understand those grown in the sandy soils of the south are much better in America than those raised elsewhere. It seemed to be a greater favourite than the common Potato, which was there called the Irish Potato to distinguish it from this one. I believe it to be more nutritious than the common Potato, and when good it turns out something between a sweetmeat and a vegetable. To import a vegetable which our climate prevents us growing, and which in consequence is a novelty to most people, is very desirable. I do not know if their price is high in America, but it would be a great boon if they could be sent here in such quantities as would allow of their being used as food. At present they are merely Covent Garden curiosities.

I do not intend at present to have any vegetables at dinner when dining in town, so wretched is the supply seen in Covent Garden during the frost. They are not merely frozen but quite decomposed! The Lettuces and Endive are only fit to be spread upon the land, and the same is true of the spotted and half-rotten Tomatoes which are now offered for sale and freely eaten in London restaurants and clubs. I fear there are some causes of death which the Registrar-General does not include in his statements.

A gentleman points out to me that it would be an advantage if the rules concerning the admission of horticulturists and others to the gardens at Kew during the hours when the gates are closed to the general public could be printed and posted outside the gate—not only at Kew Green Gate, but at the Cumberland Gate. This is so desirable that it probably has only to be mentioned to the authorities to secure their attention to it. At present persons not knowing the place may lose time or be disappointed, from not knowing what to do, as the admission is by a side gate.

Mr. Croucher tells me that trapped insects frequently injure the plants which they are supposed to "nourish." Here is his statement:—

"Anyone who, like myself, has grown insectivorous plants continuously for some twenty years, knows that they are more injured than benefited by the insects entrapped, and that the idea that they produce more seed when fed with insects than when deprived of them is a fallacy. Some assume that it is granted that all plants have the power of absorbing nutritious substances through their leaf tissues. This is also a fallacy, though it has been accepted as proved by those who only study Nature to uphold theories. How is it that plants covered with glasses to keep off flies do so well? The great cause of much of the disputation on these subjects is that naturalists

look at only one part of Nature, instead of studying her as one grand whole, seeing in the lower developments steps towards those that are higher."

The public seem to have great confidence in the gardener's skill. A gentleman was lately observed conducting a friend through a large collection of succulent plants, and telling him naively that the various forms were the result of the hybridiser's skill: "They are made to grow into any desired shape, from that of a plum pudding to a candelabrum or a tall fluted stem according to the will of the cultivator.

All those who take an interest in our markets must have noticed of late years the immense importations from abroad, to a large extent made up of hardy vegetables and fruits which could be grown quite as well in England. The question of the land, which is now the question of the day, has obviously a direct and important relation to horticulture and the supply of our markets with vegetables and fruits. There cannot be much doubt to any observing person that active and healthy competition on our side in all that concerns land produce is much impeded by laws and customs relating to the land. Now, however, when landlords themselves are found asking for reforms in these matters, there is little doubt reforms are needed. The essential thing is to carry them out wisely and effectively. One of the most sensible articles on the subject is that of Mr. Osborn Morgan in the *Fortnightly Review*, from which I quote a few paragraphs:—

The land laws of England are wrapt in a fog so dense as to make the subject intensely unattractive to the general public. Unlike our commercial code they have their origin in remote and semi-barbarous times, and are overlaid by a mass of mediæval rubbish, a legacy from that wonderful Norman race, who, to the true instincts of feudalism, united a perfect genius for legal quirks and quibbles, and who, having made themselves masters of the land of England, proceeded to write their laws upon it in characters which centuries of change and progress have not effaced.

The first stumbling-block, and, strange to say, that which might most easily be removed, lies in what is called by lawyers the identification of the parcels. It is hardly credible that, owing to the loose and dilatory way in which the recent Ordnance surveys have been carried out, there are still many parts of England, such as the populous and important county of Worcester, which cannot be said to have been officially surveyed at all; and thus, for the sake of a few thousand pounds, the landowners of England are deprived of a benefit which those of nearly every other civilised country enjoy.

To complete the all-important work of surveying every county in England, so as to make each house and field capable of immediate and unquestionable identification—to clothe instruments relating to land in the simple language of everyday life, instead of disguising them in that of Henry VIII. and Elizabeth—to pay solicitors upon a principle which would no longer put a premium upon mere verbiage—to vest the freeholds, like the leaseholds, of a deceased person in some ascertained person, instead of leaving them at haphazard to devolve upon a child in the nursery, a lunatic in an asylum, or a gold digger in Australia—to substitute simple charges upon land, defeasible in case of repayment, for the unwieldy machinery of mortgages and reconveyances—to reduce still further the time fixed for the commencement of titles—to get rid of "constructive notice" and the abomination known as the Middlesex Register—and to establish in convenient centres really well-arranged registers of all dealings with land, furnished with indexes enabling a person of ordinary intelli-

gence to pick out all the charges affecting the title in a few minutes, with proper provisions for utilising the result of previous searches, so as to obviate the necessity of repeating the same process upon every fresh transaction; all these are suggestions so homely and obvious, that they are hardly likely to find favour with a generation of law reformers who have expended as much energy upon impracticable schemes of land registration as any mediæval alchemist ever bestowed on the discovery of the philosopher's stone.

It is an axiom which no practical agriculturist will controvert, that the returns which can be obtained from any given quantity of land are in exact proportion to the amount of capital expended upon it. But as it is obviously for the interest of the community that every acre should be made as productive as possible, it follows that no system can be really beneficial which hands over a large proportion of the land to the tender mercies of a limited owner more or less crippled or impoverished, or still worse, of some usurer or loan society, whose interest it is to spend as little and get as much as possible during their precarious period of tenure.

The question has its social as well as its economical side, and of late years that large and increasing body of Englishmen who believe that the prosperity of a nation is bound up with "the greatest happiness of the greatest number," and who for years have been contrasting the lot of the thrifty and self-reliant peasant of Switzerland or Belgium, and that of the Dorsetshire labourer with no solace but the beer-shop, and no refuge in old age but the parish workhouse, have been steadily coming round to the conviction that the real hope of England lies in the growth of small proprietorships. Those who, like myself, have seen the difference which the possession of a freehold cottage and half an acre of garden makes in the habits and character—nay, in the very expression and bearing, of a Denbighshire collier, or a Merionethshire quarryman, will need no additional arguments to convince them of this great social and political truth.

The difficulties of attacking the growth of so many centuries are indeed great—to those who know the mass of prejudice, and the *vis inertiae* which the most urgent and moderate of land law reforms have hitherto encountered, they may seem insuperable. But we know that in England public opinion, when it is once set going, moves with a force and velocity which no one could have predicted, and of the direction in which it is at present moving there can be no doubt. Let us hope that the work, when it has to be done, may fall into the hands of men armed with that knowledge which a study of the subject in its practical bearings can alone give, and at the same time untrammelled by the professional and other prejudices which such a study too often engenders.

JUSTICIA.

Storing Ice.—The best method of storing ice has frequently been discussed, and one would imagine, from the minute instructions which one reads in gardening works on this subject, that it is a very complicated affair; but my own experience leads me to think that many of the supposed aids to its preservation are so many aids to its rapid decay. I have tried several plans, but the best I ever found was to dispense with packing entirely, and rely on getting as large a body of solid ice as possible into the house, thereby expelling the warmer air which all kinds of packing materials hold, in addition to their bulk reducing the space available for the ice. Last winter we filled a large house, built in an oval or egg shape, and that was said to be a bad structure for keeping ice. After carting the ice to the doors in the ordinary way, it was shot down and pounded fine with heavy wooden mallets; then it was wheeled into the house and again beaten down with heavy wooden beaters; and this was done until the house was quite full. No packing of any sort or kind was used in the house, but as soon as the inner door was shut the passage was

filled with straw bundles. After using a large quantity more or less during the whole season, we found, when filling it again lately, a quantity still left at the bottom. I am well aware that ice may be kept by various methods; but any one having an ordinary ice-house will find that they may keep it equally well without packing as with it; at least that is the conclusion at which I have arrived after trying both ways. For the future, I will rely on a good body of ice, put together in as solid a manner as heavy rammers can pack it.—J. G. L.

THE FLOWER GARDEN.

HERBACEOUS PHLOXES.

AMONGST plants which will grow and flower well and afford the utmost satisfaction in the worst of seasons, or during a long continuance of ungenial weather, none surpass herbaceous Phloxes. I do not think this fact can be generally known, or, if it is known, it is certainly not taken advantage of as it ought to be, because it is no exaggeration to say that Phloxes are thoroughly neglected in the majority of gardens. Of course there may be a few of them found growing in some out-of-the-way corner; but, for all that, they are still neglected, and ever will be until they are recognised as important plants for all kinds of summer and late autumn floral decoration. That they will one day be this is more than likely. Further than this, the many new varieties now gradually creeping into cultivation produce flowers which, for size, colour, and effect, would astonish those only acquainted with the old form of Phloxes. Although we have heard less about it recently, it is generally admitted that the old kinds of *Pelargonium* have been vastly improved on lately; but in this respect they have not outstripped the Phlox, and little idea can be formed by those only acquainted with the old varieties of the splendid colours and accommodating habits of the recently-introduced Phloxes. During August, September, October, and November, our Phloxes have been objects of general admiration, and nearly all who have seen them have gone away with the intention of introducing them into their gardens more extensively than hitherto. In doing this no one will be wrong, as no plants are more easily cultivated. None will remain so long in bloom, even in a bad season, and few are more showy. We have had flower spikes lately from 20 in. to 2 ft. in length, about as much as this in circumference, and sweetly-scented. Of course, such spikes are much too large to cut whole for any kind of cut-flower decoration, but the small side spikes can be cut off and thinned out without impairing the beauty of the spike, and these small bits do well for mixing with other cut flowers.

Phloxes are propagated either by cuttings or by division of the roots. The latter plan is the most simple and effectual. At the present time, or as soon as they are out of bloom, they should be cut down close to the ground, and after that the roots may be lifted and divided at any time during the winter. We have divided and planted them now, and we have done the same in the month of March, and both batches did equally well. When lifted now and replanted, the crowns should be covered well over with litter for the winter, but established plants do not want so much as this attention. The soil in which they delight is of a deep rich character, and before planting their quarters should be well dug and manured. When this is done before planting, no more will be wanted for some years, and then the best plan is to lift the whole of the roots, manure the ground thoroughly, and replant. Many surface-dress them, and cut the roots to get the manure closer to them, every winter; but when the ground has been properly prepared at first, this kind of cultivation is unnecessary. When new plants are bought in from a nursery, which is the best way of introducing new kinds or adding to a collection, they are generally received in small pots. These should be got in, and planted early in spring, when they will produce a good display of bloom in autumn. As to the right situations in which to plant Phloxes, they are never out of place anywhere. A mass of one colour or another may be had in any bed in the flower garden, or all kinds may be mixed together in herbaceous borders, shrubberies, or by woodland walks. Space need not be taken up enumerating names of the best varieties, as selections for all purposes may always be made from trade catalogues.

CAMBRIAN.

Permanent Bulb Beds.—As almost all kinds of bulbs may yet be planted, I would advise any one fond of that class of plants to try the following method of disposing of any surplus bulbs which may be left after the show beds or geometrical gardens have been planted. Select positions for them on the lawn or pleasure grounds where branches of Lime or other deciduous trees cause the Grass to grow thinly and weakly, and where the mowing machine is not a regular visitor. After deciding on where the clumps or patches of bulbs would look best, break up a few spade-

fuls of earth, and if poor add a little fresh soil, and plant bulbs of the earliest flowering kinds, such as Snowdrops, Crocuses, Aconites, Daffodils, Jonquils, and Bluebells. They will come up in spring and will look all the better for being associated with the young foliage of the Buttercups and Daisies that are seen to mingle with them, and by making a selection of sorts that bloom in succession a pretty effect may be obtained in this way for many weeks. After the foliage dies down the scythe may be run over the surface, which may be otherwise treated as the rest of the lawn. We have a great variety of bulbs under trees, and lovely they look when in bloom. Some are planted so as to form designs, but I prefer them in irregular groups or masses that are allowed to extend at will, as, except for the purpose of increasing the stock, they are best left undisturbed. The Daffodil does well planted on open spaces in the turf, but in such positions as those just named a very large variety of bulbs may be grown most successfully.—*J. G., Linton Park.*

DRACÆNA AUSTRALIS IN WILTS.

THE accompanying engraving represents a good specimen of *Dracæna australis* in bloom in the flower garden of Mr. N. F. Barton, Corsley House, Warminster. This plant has been growing in the open garden upwards of twenty years: it measured, when in blossom, about 9 ft. in height; the bloom-spike was 4 ft. 6 in. in length, and

Dracæna australis in Wilts.

5 ft. through at the base or at the broadest part; the fragrance emitted from the flower perfumed the air for some distance around. It has flowered frequently, and on one occasion ripened seed, from which I have a fine vigorous seedling planted out in the nursery. Mr. Barton's garden faces the south, and is sheltered on the north-east side by a high wall, near which the *Dracæna* is growing; the soil is light, with a dry porous subsoil.

G. B.

Hardiness of *Fuchsia procumbens* (p. 465).—Mine stood out all last winter, without any protection, under a wall, and raised a few inches above the walk. A friendly stone, a few inches high, may have constituted a slight shelter. It suffered severely, and was cut back to the crown; but, when warm weather set in, it threw out its long trailing shoots as well as ever. It may not be out of place to remark here that, in cases of all plants of doubtful hardiness, I make a point of planting them out in spring, in order that they may have a whole season before them, and so get well established before winter. I would not think of planting *Fuchsia procumbens* out now, but would do so without hesitation next April or May.—*EDWIN JACKSON, Llandegai.*

SPRING GARDENING.

A CORRESPONDENT in the south of Ireland has sent us the following account of the way in which his spring garden, consisting of sixty beds, is stocked with plants to bloom next spring:—

- 1.—An oval contains sixty mixed single early Tulips, and is edged with a border of *Triteleia conspicua*.
- 2.—A scroll is furnished with thirty-six double early Tulips of the Duke of York variety.
- 3.—An oval is filled with twenty-two varieties of choice named hybrid Daffodils, edged with Golden Point Lace Pyrethrum.
- 4.—A scroll planted with *Iberis superba*.
- 5.—An oval containing a carpet of *Myosotis dissitiflora* with fifty early double Tulips of the yellow rose kind edged with *Triteleia conspicua*.
- 6.—A square filled with twenty-five *Tulipa Greigi*, edged with a thick border of *Narcissus odorus plenus*.
- 7.—An oval with ninety-six early single Tulips, consisting of six varieties with gold and silver variegated foliage.
- 8.—A crescent with eighty-two mixed single early Tulips.
- 9.—A diamond with *Fritillaria imperialis* (Crown Imperial) consisting of seven varieties, edged with fourteen varieties of Leeds' Hybrid Narcissi.
- 10.—An oval with fifty English Irises, consisting of twenty-five varieties, carpeted with nine varieties of Nelson's Hybrid trailing Phloxes, and edged with *Narcissus odorus plenus*.
- 11.—A smoothing iron with thirty-one named single Hyacinths, edged with *Narcissus minor*.
- 12.—A crescent with single French large-flowered Anemones.
- 13.—A crescent with 300 offsets of single early Tulips, and fifty-one roots of named varieties in three kinds intermixed.
- 14.—A smoothing iron with thirty-six early blue Roman Hyacinths.
- 15.—An oval with seventy-five named bedding Pansies in three varieties, edged with a thick border of *Anemone nemorosa alba plena*.
- 16.—A circle with forty-eight double Rex Rubrorum, and the same number of *La Candeur* round them, and edged with *Narcissus minor*.
- 17.—An oval with Dean's Hybrid Single Primroses, edged with *Narcissus odorus plenus* or the Crown Jonquil.
- 18.—A star with fifty double Hyacinths edged with *Narcissus Eystettensis plenus* or Queen Anne's Jonquil.
- 19.—A smoothing iron with a carpet of Nelson's Hybrid Phloxes in nine varieties, twelve *Lilium colchicum*, and two *Lilium Batemanni*, edged with Queen Anne's Jonquil.
- 20.—An oval with Lothair blue bedding Pansy, and a centre of Captain Hayter yellow bedding Pansy edged with *Colchicum autumnale flore-pleno*.
- 21.—A circle with 400 Meladores, edged with *Colchicum autumnale flore-pleno albo*.
- 22.—A crescent with eighty mixed single early Tulips.
- 23.—An oval with yellow bedding Pansy The Shah, with white bedding Pansy Mrs. Turner in the centre.
- 24.—A raised Mushroom with Nelson's Hybrid Phloxes in nine varieties.
- 25.—An oval planted the same as No. 5 bed, but edged with *Narcissus minor*.
- 26.—An oval with Waverley blue bedding Pansy.
- 27.—A square with twenty *Tulipa Greigi*, edged with *Triteleia conspicua* and lilacina.
- 28.—A star with 200 scarlet Turban Ranunculuses in centre with 300 white Hercules Turban Ranunculuses round them, edged with *Narcissus minor*.
- 29.—An oval with choice double Pyrethrums in eighteen varieties, carpeted with eighty double Van Thol Tulips, edged with Mammoth yellow Crocus.
- 30.—A scroll with thirty-six double Tulips of the *Mariage de Ma Fille* variety, edged with double white Primroses.
- 31.—An oval with bedding Pansies Golden Bedder, Imperial Blue, Pilgrimage White in rings, with dark *Viola Acme* in the centre of the bed.
- 32.—A circle with eighty-four single Tulip *Couleur cardinal*, edged with *Anemone nemorosa alba-plena*.
- 33.—An oval with forty-eight English Irises in thirteen varieties, edged with *Triteleia conspicua*.
- 34.—A scroll with thirty-six single Tulips of the Kaizer Kroon kind.
- 35.—An oval with blue bedding Pansy Waverley.
- 36.—Mushroom with trailing Phloxes Nelsoni, setacea, and *atropurea*.
- 37.—An oval with mixed bedding Pansies in six varieties, edged with named Crocuses, also in six varieties.

38.—A scroll with *Iberis superba*, edged with *Pyrethrum Golden Point Lace*.

The following twenty-two small beds—all circular save one which is square—are filled as follows:—

1.—Six Tulips of the *Bruid Von Haarlem* variety, edged with *Crocus byzantinus*.

2.—Six Tulips *Yellow Rose*, edged with *Campanula garganica*.

3.—Six Tulips *Vuurberg*, edged in the same way.

4.—Six Tulips *Roi Pepin*, six *Allium Douglasi*, six *Erythronium grandiflorum purpureum*, edged with *Crocus Ne Plus Ultra*.

5.—Six Tulips *Roi Pepin*, edged with variegated *Myosotis elegantissima*.

6.—Six Tulips *Golden Standard*, edged with *Crocus Madame Mina*.

7.—Six Tulips *Yellow Rose*, edged with double *Daisy Little Dandy*.

8.—Six Tulips *Proserpine*, edged with *Crocus Miss Nightingale* and *Aubrietia variegata*.

9.—Six Tulips *Roi Pepin*, six *Seubertia laxa maxima*, six *S. atropurpurea*, twelve *S. laxa*, three *Milla longipes*, edged with *Arabis lucida variegata*.

10.—Six Tulips *Roi Pepin*, edged with a thick border of *Silene alpestris*.

11.—Six Tulips *Vermilion Brilliant*, edged with autumn-blooming *Crocuses*.

12.—Six Tulips *Bruid Von Haarlem*, edged with *Campanula turbinata*.

13.—Six Tulips in three varieties, edged with *Silene alpestris*.

14.—Six Tulips *Proserpine*, edged with *Crocus Sir Walter Scott*.

15.—Six Tulips *Proserpine*, edged with *Camassia esculenta* and *Fraseri*.

16.—Six Tulips *Silver Standard* with *Albion Crocus* round, edged with *Aubrietia*.

17.—Six Tulips *Vuurberg*, edged with *Crocus lilacinus*.

18.—Six Tulips *Elenore*, edged with *Campanula turbinata*.

19.—Six Tulips *Golden Standard*, edged with *Hesperocordum lilacinum*.

20.—Fourteen Tulips *Silver Standard* round seven *Hyacinthus candicans*, with *Eremurus robustus* in centre, edged with *Aubrietia variegata*.

21.—Two *Fritillaria pallidiflora*, three *Fritillaria recurva* in centre, two new species of *Allium*, edged with *Silene alpestris*.

22.—*Fritillaria Thomsoniana* in centre, *Muscari paradoxum* round it, *Narcissus Maeleayi* and *serrulata*, edged with *Lilium Thunbergianum alutaceum*.

The above will serve to show what a really well-stocked spring garden ought to be.

The Great Lizard Orchis.—Referring to two recent notes on this subject (pp. 445 and 462), let us hope that "students of British wild flowers" will not be too hasty in "adding one more to the few habitats" of this rare Orchis. Let the question by all means be decided next June by sending a flower to the Editor of THE GARDEN. I venture to predict that it will turn out to be *Habenaria bifolia*, which is found sparingly both on the Great and Little Orme, being less common there than in most other parts of North Wales. This plant was not mentioned in the strange medley of common and uncommon plants first given by "Botanist" as occurring on the Great Orme's Head. To believe that *Orchis hircina* is really found there is to suppose that the many experienced botanists who have searched the Orme's Heads at all seasons have been without eyes.—C. W. D.

Gypsophila paniculata.—In answer to Mr. Ewbank (p. 507), allow me to say that I am aware that many chalk plants will grow in common soil, and so will *Watercress*. What I wished to point out was that peat was unnecessary for a chalk or a limestone plant, and what I thought strange was that there should be any difficulty about the culture of a plant that I have discarded on account of its superabundant growth and its sprawling and monopolising propensities. I have no doubt that this plant may sometimes suffer from not being sufficiently elevated. Its profusion of stem and spray falling on itself may, on a dead level, perhaps injure it. The very aerial look of the plant bespeaks its adaptation for an elevated position; and I have no doubt the proper way to grow it would be to make a mound of a barrow-load or two of stones, fill up, and plant it in ordinary stony soil, and leave it alone to ramble at will. In such a situation I have no doubt that it would do better than on a level surface, though smothered or buried in peat. It is certainly not a plant for ordinary border culture, and tying up such a plant would be folly. As a finishing or feathering to bouquets it may be admissible, but I have never seen it used in any bouquets, though some of the choicest in the world are made in our neighbourhood. There is, however, a difference between a bouquet and a mop. The sprays of *Gypsophila*

paniculata are too open and diffuse for a neat nosegay, but it answers for vases and such like decorative work, and I always made use of it to feather up baskets of cut flowers at our country shows. The plant even dries and keeps better than some *Staticee*, and in masses it has a charming appearance in grates and urns in winter; and could Mr. Ewbank but see it thus used, his advice about putting it in the fire would have been unnecessary. Dried and bleached white this plant enters largely into importations of dried flowers.—THOMAS WILLIAMS, *Ormskirk*.

SHOWY MEADOW RUE IN THE WILD GARDEN.

Showy Meadow Rue in the Wild Garden.

AMONG plants which one never sees, and which, indeed, one never ought to see, in a flower garden, are the generality of *Rues*. Before the advent of the little Maiden-hair *Window Rue* one never saw one of these in a garden, except, perhaps, in that of some person who got it in an ill-assorted collection of hardy plants, but did not keep it after he had discovered his mistake; and yet there is a quiet beauty and grace about these plants which entitle them to some consideration; and the flowers, too, of certain species, particularly the one shown in our illustration (*Thalictrum aquilegifolium*), are of singular beauty at a certain season; and, when it is considered that all the species will grow anywhere—in any hedgerow or lane or byeway, or among

coarse Grass or in a copse, or under the shrubs, in places usually devoted to common weeds, there is no reason why numbers of them should not be rescued from the ob-

livion of the botanic garden and grown carefully near a garden or house; if so grown or placed they would look infinitely more graceful and beautiful than in the stiff arrangement of a botanic garden. Here, however, is a little illustration showing one kind, sketched at Longleat, and which, indeed, should have been inserted in the account of that place a fortnight ago.

Yucca gloriosa and recurva.—Amongst fine-foliaged hardy plants suitable for the embellishment of the outdoor garden at all seasons of the year, few can surpass the well-known *Yucca gloriosa*, with its stiff, rigid leaves tipped with sharp spines; and its graceful and appropriately named companion, *Y. recurva*. They commend themselves to one's notice in many ways; for instance, they are thoroughly hardy, easily propagated, and by no means fastidious as regards soil or position; and their strong, wiry roots, and equally tough foliage, render them proof against injury from rough winds. They produce suckers by means of which young plants are easily procured, and if required for vase decoration, or for central objects in beds of flowers or succulents, or in connection with hardy shrubs for winter effect, they should be grown in pots and plunged in the reserve garden when not required for use. Well-furnished specimens in 8 in. or 10 in. pots are extremely useful for indoor decoration, and especially for mixing with other plants in groups or floral decorations in winter where tender stove plants would be liable to receive injury. They are about the best of subjects for planting permanently in geometric gardens for furnishing circular beds, forming as they do such fresh looking objects at all seasons of the year, and being extremely ornamental when in flower. After flowering, however, they lose their symmetrical proportions, and branch into many crowned heads, a condition in which they look well as a background for borders devoted to fine-foliaged plants, giving as they do a kind of aspect to any arrangement of this sort not attainable by other plants that will withstand our winters. We have them in quantity mingled with the *Chusan Palm* and similar plants; they flower freely every autumn, and during winter they are always acceptable and prominent subjects amongst hardy fine-foliaged plants.—J. GROOM, *Linton, Kent*.

NOTES OF THE WEEK.

Salvia leucantha.—Mr. Gumbleton informs us that this plant is now one of the charms of his greenhouse, every bit of branch flowering profusely. It is somewhat shrubby, and the leaves, which are wrinkled, resemble those of *Buddleia globosa*. The flowering shoots are covered with a dense purplish down, which, with the pure white corolla set in the deep violet-purple calyx, gives the plant a delicate and novel appearance, and renders it a highly desirable decorative subject.

The White-flowered Lycaste Skinneri.—This extremely rare Orchid will in a day or two expand its chastely beautiful waxy-white blossoms in Messrs. Veitch & Sons' nursery at Chelsea. This novelty is all the more valuable on account of its being one of the cool house section, and apparently as amenable to ordinary treatment as the type, which, with its numerous varieties, has become so popular.

A Golden-leaved Jasmine.—On Mr. Rutland's house at Goodwood there is a large surface covered with a plant of the common Jasmine, which is freely variegated with rich golden-yellow, some of the young shoots being of the same colour, with the exception of a small strip of green. As a variety of our well-known and favourite Jasmine it may be worth increasing.—H.

Roses at Goodwood.—There are some superb examples of Roses at Goodwood trained on the pegging-down system; each specimen covers many square feet of ground, and the flowers are produced by the shoots that are pegged down, those to be pegged down in their turn for next year's bloom being allowed to grow in the centre. The effect of specimens thus managed, as compared with standards or half-standards, is most satisfactory.

Lasiandra macrantha.—There are many examples of this fine stove shrub at Goodwood now producing their rich purple flowers, which are extremely pleasing and effective in a somewhat cool stove, a temperature most agreeable at this time of the year. This *Lasiandra* is a very valuable winter-blooming plant.

The Rough-leaved Dianella (D. aspera).—Berry-bearing plants in general commend themselves to notice at this season when flowers are somewhat scarce, and this handsome Australian plant is certainly one of the most ornamental for greenhouse decoration. It grows about a yard high, and has woody stems terminated by a tuft of lance-shaped leaves. The flowers are small and blue, borne in panicles during summer, and are succeeded by dark blue berries, which resemble in size and consistency the North American Snowberry. It may be seen in the Temperate House at Kew.

Begonia peruviana.—To Mr. Gumbleton we are indebted for flowers of the remarkable, and, as we think, very handsome and distinct *Begonia peruviana*, which was originally sent out as a variety of *B. octopetala*. It certainly seems a very fine winter blooming plant.

Billbergia vittata macrantha.—In the Palm House at Kew this splendid new variety is now very attractive. It has rich purple blossoms borne in long, drooping racemes furnished with numerous scarlet membranous bracts, which have a very showy appearance. The foliage, too, is very ornamental, as it is marbled and transversely marked with greyish hue on a bronzy-green ground. It is known in some collections under the name of *B. farinosa*.

New Hybrid Lady's Slipper (Cypripedium albo-purpureum).—Of the numerous hybrid Lady's Slippers that have emanated from Messrs. Veitch & Son's establishment during the past few years, there are few handsomer than this one. It is the result of a cross between the pretty little *C. Schlimi*, with deep rosy-tinted flowers, and *C. Domini*, itself a hybrid between *C. caudatum* and *C. Pearcei*. The flowers of *C. albo-purpureum* are somewhat similar in tint to that of the popular *C. Sedeni*, but with considerably more white intermixed, and the flowers, which are larger, are characterised by long twisted tail-like segments, which render it highly attractive and well deserving of a place in every choice collection. In the note last week on *Cattleya Domini* the parentage was given as *C. labiata* and *C. amethystina*, whereas it should have been *C. maxima* and *C. amethystina*.

Bouquet Flowers.—I noticed some very handsome bouquets in Warren & Craik's shop, in Jernyn Street, the other day, composed of white flowers with a sprinkling of a beautiful pink *Pelargonium* amongst them. The *Pelargonium* was the kind called Mrs. William Paul, and the combination struck me as being particularly pretty.—J. H.

Roses on Trees.—We were greatly pleased at Winton to notice a very sensible and artistic use made of the more vigorous climbing Roses by training them up the bare stems of Pines and

other trees. The effect was excellent, even late in November. I have seen the same thing carried out before, but never saw it so well done or the Roses so vigorous and high as here. A list of the kinds that have succeeded best will be found in THE GARDEN of last week (p. 510).

The Imperial Dahlia (D. imperialis).—Of this magnificent species we have lately seen some fine examples in the Palm House at Kew. It would not be recognised as a Dahlia at all, as it is so unlike the ordinary flowers bearing that name, though it resembles considerably the single flowered varieties of which we have of late heard so much. The large white crimson-eyed and gracefully drooping flowers of this species possess a beauty which far surpasses that of the other varieties, and its majestic appearance is much increased by being borne on stems about 10 ft. high. On the other hand, its great height renders it unfit for any but lofty houses, where there is ample room for its development, as it is unfortunately late in the season before it commences to flower, though it may be grown in the open air throughout the summer and early autumn. A coloured illustration of this noble plant is given at p. 352, Vol. XII., of THE GARDEN.

Coriaria ruscifolia.—Being at Kew the other day and observing this shrub, which you justly note for its beauty of form, I happened to detect for the first time its peculiar floral structure and development. The fruit appears to be a berry, but it is not so, and very curiously it is the petals only that produce the resemblance. When the flowers open the petals are small and green, though fleshy; afterwards they swell, become purple, and enclose the ripe carpels. On first inspection it might be supposed that the purple mature petals are carpels that have separated from each other, exposing seeds at the base; but on examining the parts during different stages it is easy to notice that the apparent seeds alone result from the pistil. This species is a native of New Zealand, where it is called "Tutu." The berries yield a purple juice much liked by the natives, but which soon ferments. A wine made from it is said to taste like Elderberry wine. The seeds are poisonous, producing convulsions and death. I have not seen this species fully exposed, but *C. myrtifolia* makes a handsome bed, though the branches are cut by severe frost.—L.

New Hybrid Nerines.—The Pine-apple Nursery, Maida Vale, is notably rich in all kinds of tender bulbous plants, and visitors to it may invariably find something in that way in flower throughout the year. At present the most conspicuous amongst them are the beautiful hybrid Nerines, the result of Mr. O'Brien's manipulation. The majority of the species of Nerines are, in their pure and simple state, very beautiful, but one of these hybrids—which, by the way, is unnamed—far exceeds in softness and richness of colour any that we have hitherto met with. It is the result of a cross between the old but little known deep rosy-pink *N. flexuosa*, which is such a charming plant for greenhouse decoration in winter, and the earlier-flowering *N. Fothergilli* major, whose brilliant crimson flowers charm every one who sees them. The hybrid in question partakes in a striking degree the characteristics of both parents, and especially as regards the colour of the flowers, for the glaring vermilion tint of *N. Fothergilli* is toned down, as it were, by the soft rosy hue of *N. flexuosa*, the result being a most pleasing delicate carmine, a colour rarely met with in flowers. Other hybrids here are very pretty, but not so striking as that just named; but all are well deserving of attention, on account of their adaptability both for greenhouse decoration and for cutting purposes, for which the flowers are very suitable, as they are developed on long stalks. This and various other classes of plants which have gone out of fashion ought to be more generally grown than they are, helping, as they do, to break that monotony which the culture of only a limited number of plants invariably produces.

Lectures on Fruit Trees in Paris.—M. Forey, a distinguished member of the Paris Horticultural Society, gives every year a free course of public lectures on the culture of fruit trees. The course for the ensuing year will include the following heads:—Pruning; Economical Methods of Production; the Culture of Peach and Pear Trees at Montreuil, and of the Vine at Thoméry. These lectures will be illustrated by practice in an adjoining garden. When, let us ask, will matters of this kind receive similar attention in this country?

The Nurserymen and Gardeners' Annual Dinner, which took place the other day in Edinburgh, seems, from the account given of it in the *Edinburgh Courant*, to have been a most interesting meeting, attended by most of the head gardeners and leading nurserymen in that neighbourhood. Various speeches were made, and amongst them one on the Royal Caledonian Horticultural Society, which was stated to be the first Society that paid its prizes in cash on the day on which the show took place, and also to be the first that had held an international show.

COUNTRY SEATS AND GARDENS OF
GREAT BRITAIN.

GOLDER'S HILL.

WHILE one thinks of the saddening result of what is called landscape gardening, as shown in some of the largest and most pretentious places, it is some consolation to know that here and there a small one exists in which some natural and artistic beauty may be found. The big water-squirts, the coloured gravels, the tortuous and unmeaning geometry cutting up the foreground; the want of freedom and of breadth, owing to frivolous designs; the varied rubbish in terra cotta and artificial stone; the barren rectangular style, illustrated in many show places; the brand new "mediæval" fosse, dissecting and destroying all repose, as at Coombe Abbey—many such things one could enumerate, and they are too common. But places where the simple and essential conditions for the most perfect beauty in planting and design are understood or illustrated are far too rare. It is all the more pleasing to meet with an example of simple and most artistic treatment of a garden almost in London, for Golder's Hill is within five miles of Charing Cross, on the western border of Hampstead Heath. As regards design and views, it is the best garden with which I am acquainted in or near this sooty Babylon, and the conditions of its beauty are so simple that there is really little to be said about them. An open lawn there is, which rolls up to the house like a carpet; groups of fine trees, and wide and distant views over the country north of London. On entering the garden, indeed, one is astonished at the extent and beauty of the view and the gradually receding distances.

A sunken fence separates the lawn from some park-like meadow with fine Oaks and Firs, and beyond the country north of London opens up, without any building visible on either side or in the foreground. Our view is from a photograph by Mr. Vernon Heath, which, though beautiful, does not show the breadth of the lawn as much as could be desired for our special purpose. Another engraving, from a sketch showing a view from the house, we hope to have the pleasure of issuing on some future occasion. Our view shows in the foreground certain remains of an old avenue that were left by Mr. Marnock. A walk passed up between these trees, which was done away with, and the green Grass touches their boles at present. From almost every other point of view these trees seem to form a picturesque group, and afford a welcome shade in summer. The whole of the front of the house, it must be understood by those who have not the opportunity of seeing the place, is an easy and perfect lawn, which one can step on to at once without any *impediments* of the kind usual in such places. Being on a gentle rise, the ordinary landscape gardener would no doubt have urged this as an additional reason for making some kind of fortification in the shape of a terrace garden, which would have destroyed the repose, verdure, and the freedom of the spot. However, he never wants a hillside as an excuse for his terrace, because he would make it in a Lincolnshire fen as readily as anywhere else. Here, the house originally seeming to follow the drop of the hill a little, it was considered necessary to have a very small terrace, which, however, is not a regular one, but runs on one side into the ground imperceptibly, and does not in the least interfere with the ease of movement from the house to the carpet of green.

Now the only drawback—if drawback it be to such perfect freedom and breadth of airy foreground—is the fact that it offers a continual temptation to unthinking people to dot it over with flower beds, or allow evergreen trees to be planted almost nursery fashion. Many places, originally well laid out,

are spoiled by this thoughtless dotting about of objects which please the eye for the moment. The question of flowers is the greatest difficulty, because people are so well accustomed to have all their flowers gathered in front of the house, that, if abundant provision is not made for them elsewhere, the carpet is apt, some day or other, to be dissected into a number of ugly flower beds. The best way to guard against this is to provide abundance of simple beds elsewhere, which, half seen peeping through the trees, or met with in groups here and there at no great distance from the house, afford better effects in flower gardening than can be obtained where all the beds are stereotyped under the windows. Thus, where the foreground is a pleasant lawn, it is necessary to have one spot which may answer for the flower garden; and, better still, large isolated beds or groups of beds, in which special subjects can be grown, as they are never grown in the ordinary flat flower-garden, which leads to uniformity in height and otherwise. To have here a group of large beds, simple in outline, with Roses and smaller plants surfacing the ground; next, in some isolated nook, a large oval bed of Lilies, separated by a group of low shrubs and flowering Yuccas from a few beds of hardy florist flowers; then a varied flower garden partially cut off and embowered by trees—these and the like are much better than the usual stereotyped floral rug which is spread before the door. While, therefore, we have so much to praise in the design of Golder's Hill, it is somewhat deficient in provision for flower gardening, which would reconcile all to the sweet repose and ease of the lawn.

The engraving shows the garden front of this house at Hampstead, or rather in Hampstead and Hendon, for the parochial boundary runs through the house and across the lawn. It has been known for many years past as Golder's Hill, and is now the family residence of Mr. Spencer Wells, the eminent surgeon of Upper Grosvenor Street, who purchased an old house and about 40 acres of freehold land surrounding it, and bordering on Hampstead Heath, about ten years ago. The old house still remains, with woodwork and decorations of the Scotch architect Adam, who built the Adelphi, and did so much work in the district of Cavendish Square. Additions have been made to it at four separate periods; but the present aspect was given to it in 1875 by Mr. E. F. Clarke, the architect who advised Mr. Wells in the erection of the wing next the conservatory (the roof of which is seen in the engraving covered by Ivy and shaded by an old Yew), the roof and verandah, and the bay which replaces the old plain front of the east wing. The arrangement of the conservatory, of the connecting covered way between the conservatory and the house (not seen in the engraving), and of the terrace, is due to Mr. Marnock. Mr. Clarke has been unusually successful in his effort to harmonise the lines of the building—especially the gables, roof, and chimnies—with the fine old trees which surround the house and make up an artistic picture; and Mr. Marnock, by his arrangement of a broad level terrace, has quite removed the unpleasant effect which the old house produced (from being built on sloping ground) of slipping down hill. We have often pointed out the advantage of associating the landscape gardener with the architect in the choice of a site and in the elevation of new buildings; and the present is a conspicuous example of the good effect obtained by similar co-operation in the case of additions to and alterations of old houses and grounds.

Hampstead has long been renowned as a health resort, and North End especially so, as it is open to the south and west and sheltered from the north and east, with views extending from Windsor and Harrow to Edgware and Barnet. More than 100 years ago, Akenside, the author of the "Pleasures

of Imagination," in his ode on "Recovering from a fit of sickness," wrote, in 1758 :

Thy verdant scenes, O Golder's Hill !
Once more I seek, a languid guest.* *

How gladly 'mid the dews of dawn,
By weary lungs, thy healing gale,
The balmy west or the fresh north inhale !
How gladly, while my musing footsteps rove
Round the cool orchard or the sunny lawn.
* * * * *

Akenside practised more than two years in Hampstead as a physician before he went to London and became physician to St. Thomas's Hospital. His friend Dyson bought a villa at Golder's Hill, and it was on a visit to him that Akenside

recognize the hand of Brown at once, and Mr. Marnock is of the same opinion.

About a hundred years ago the house and some part of the land in Hendon belonged to the celebrated David Garrick. It is not known if he lived in it ; but there are letters of his wife extant, dated "Hampstead." This must have been before he purchased the house at Hampton where he died. Mr. Wells has his signature on two deeds which came into his possession on purchasing the property.

William Howitt's pleasant book, "The Northern Heights of London," is full of historical and biographical reminiscences of former residents around Hampstead Heath, and it contains an interesting account of successive enclosures by

GOLDER'S HILL (SIDE VIEW OF LAWN).

From a Photograph by Vernon Heath.

recovered his health. It is curious that Akenside should have taken his degree of Doctor of Medicine at Leyden, and that a century later the University of Leyden, at its third centenary, should have conferred its honorary degree upon the present owner of Golder's Hill. It must have been about the time of Akenside's visit that the grounds of Golder's Hill were laid out and planted by Capability Brown. There is no direct evidence that he did this, but he is known to have laid out several other places in the district ; and there are certain distinctive peculiarities in the manner in which boundaries and walks are concealed, old avenues broken up into clumps, natural water courses banked up to form ornamental sheets of water, and groups of Sycamore, Sweet Chestnut, Beech, and Birch planted to contrast with Poplars and much older groups of fine old Oaks and Elms, which led the late Mr. Gibson to

lords of the manor of parts of the Heath, and of the contests with the inhabitants, which led to the final stoppage of all encroachment on public rights, and the securing to the nation for ever of this most beautiful of our open spaces by Act of Parliament. Since the Metropolitan Board of Works has been entrusted with its custody, a good deal has been done towards its preservation ; some planting has been successfully carried out, and a beginning has been made in the way of road making and improvement of paths, which, we trust, may be carried on to the general benefit of the district. There is still room for much to be done in this way without any interference with the natural aspect of the Heath ; but this is a subject to which we must devote a special article hereafter. Those who wish for further information about the houses near the Heath may consult Howitt's book for an

interesting account of Lord Erskine, who lived in a house close to the "Spaniards," where, "during the interval of his arduous professional labours, he was zealously engaged in carrying out his improvements. With his old gardener, John Barret, he took his spade, and schemed and dug, and planted and transplanted, and no one who has not tried it can tell the immense refreshment of such an entire diversion of otherwise exhausting trains of thought." Near Erskine lived two other great lawyers, Mansfield and Loughborough, and at North End, in a house now the residence of Mr. Haynes, Lord Chatham found a temporary retreat in 1767.

The views from Hampstead Heath and Golder's Hill northwards over Finchley, Mill Hill, and Edgware; westward across the Willesden and Harrow distinct; and southwards towards Windsor and Sydenham, are especially fine, both in the early morn and towards sunset. Burke was greatly struck with the sunset view when walking with Erskine. "Ah! Erskine," he said, "this is just the place for a reformer; all the beauties are beyond your reach, you cannot destroy them." In one of the conversations of Reynolds and Gainsborough we find the following: Gainsborough is the speaker, and standing on Golder's Hill—"I am no friend to enclosure," said he, "yet this picture composes well; yes, beautifully! intersected as it is. But the enclosures are small, and the trees group well together; better than one usually sees from a rising ground. None but an ass would build upon a hill, unless there be hills above—unless, indeed, one could have the picture lighted up in this glorious painter-like style. Thirteen degrees of distance have I counted, all distinct. Look! Sir Joshua, how that sweep betwixt Hendon and Mill Hill reposes in dusky shade. What aerial perspective! How prismatic! 'tis like viewing Nature through the medium of a lens." And as Gainsborough and Reynolds saw it, it is to be seen now—a few more houses dotted about, the viaduct of the Midland Railway at Hendon not unpicturesque additions; but Windsor, Harrow, and Hendon, and the thirteen degrees of distance, just as they were a hundred years ago. No wonder that the district is still a favourite resort of artists, and that so many choose Hampstead as a residence, or that so many lawyers and doctors since Akenside and Erskine have chosen it for their home. These lines of Leigh Hunt are as true as the poetical prose of Gainsborough:—

Then northward what a range, with heath and pond,
Nature's own ground; woods that let mansions through,
And cottaged vales, with pillowy fields beyond,
And clump of darkening Pines, and prospects blue,
And that clear path through all where daily meet
Cool cheeks, and brilliant eyes, and morn-elastic feet.

The "morn-elastic feet" are just what so many hardworkers in town never possess, and they do find them without the fatigue of a daily railway journey by sleeping on the northern heights of our great city. The celebrated surgeon, Sir Benjamin Brodie, finding his health failing in 1823, tells us in his "Autobiography," that up to that year "I never absented myself from London for more than three weeks in the summer, and sometimes not at all. During the empty season I engaged at first a ready-furnished house at Hampstead, and afterwards had a permanent residence there, at which my family remained, and where I dined and slept, coming to London every morning after an early breakfast." This he did for fourteen years before he purchased the Surrey property at Betchworth.

We need say little more as to the situation of Golder's Hill or the views from the house. Our engraving is from a photograph taken about two years ago. Since then the appearance of the house, it may be remarked, has been greatly improved by the growth of climbing plants. On the pillars of the verandah, climbing Roses and Clematis remove all

aspect of stiffness, and in front of the steps, leading up from the terrace, we saw last week, and gathered on Monday, December 1, three fine blooms of the old China Rose, and left many unopened buds, although within a hundred yards the ice was covered by skaters. The Rose is growing amid a fine plant of a large-leaved Ivy (*Regneriana*). Close by are three Camellias which bloomed well last spring, having stood the winter better than common Laurels in the same position. A fine old plant, carefully preserved from the old building, of *Wistaria*, now reaches well up to the third story, and the old garden house, surrounded by rustic arches and covered by Ivy, is picturesque at all seasons. The winding path to the left of our picture was diverted by Mr. Marnock from between the trees to the right, where it formerly passed, in order to enlarge the lawn, to show the trunks of fine Elm and old Scotch Firs rising directly from the Grass, and to open up the whole front to light and air by the removal of a shrubbery. In order to bring ornamental water better into view from the house, advantage was taken of necessary alterations of level to form a bowling green, and in several other instances Mr. Marnock's taste for natural gardening has been most successfully acted upon. A formal rectangular pond, with a high, ugly, and dangerous bank, has been enlarged into a sheet of water of sufficient size to afford plenty of room for skating, with a graceful outline, the ends skilfully converted into an inlet and an outlet under rustic bridges, giving the appearance of a stream, and with masses of shrubs so planted on the sloping banks as to remove all feeling of artificial stiffness or uniformity. Many trees, originally planted as nurse trees, but left to injure the finer specimens they were intended to protect, have been felled. Others, dead or decaying, have been removed, and planting of some of the best varieties of the Conifers recently introduced, with ornamental deciduous trees of different habits, and flowering shrubs, has been so judiciously planned and executed, that in a very few years time the natural beauties of the spot eulogised by Gainsborough, Burke, and Hunt will be more and more enhanced by Art. The wild garden in this year's planting is receiving more attention, and Mr. Alfred Parsons has already made sketches in parts of the grounds, which in due season we shall bring before our readers, as happy examples of what may now be found in some of our British gardens, and we hope will, before long, be found in many more. W. R.

Garden Labels.—The best of labels must always be unsightly and incongruous; and amateurs can avoid their use entirely in permanent herbaceous borders, Roseries, and Alpine gardens or rockeries by the use of a cardboard plan for each separate part; if this is carefully made originally, it will be found that there is not the least difficulty in at once identifying the plants. I have found this arrangement work admirably; it is especially useful when planting any fresh specimens in an already crowded border, as any vacant space can be easily selected by reference to the plan, and thus bulbs or other plants at rest are often saved from a cruel and damaging thrust from the trowel. There are, however, still many cases in which the use of labels is unavoidable, and then the aim should be to select the most permanent, and, at the same time, least obtrusive kind which can be devised; to endeavour to meet this view, I have for some years past used a "combination label," which has answered every purpose most satisfactorily; it is made in the following way, viz., A few pounds of galvanised iron wire from 1-16th to 1-8th in. thick, are cut into lengths of about 16 in.; a small loop is twisted at one end, and a supply of Maw's 1½-in. circular labels is hung on and the loop closed. The combination of hundreds can be thus effected in a short time. In using these labels it is well to press the wire into the ground, so that the label is almost touching the ground. Ordinary writing with a hard and sharp pencil will last for many years, and even then, if dull, can be renewed in a few seconds, certainly far simpler than the label suggested by Mr. Williams, which was fairly criticised in a recent number as "too complicated." I hope, therefore, that my label may prove of some use to my brother amateurs.—A. KINGSMILL, *Eastcott Cottage, Pinner.*

THE GARDEN FLORA.

PLATE CCX.—PRIMULA CAPITATA.

Drawn by W. H. FITCH.

HIMALAYAN PRIMROSES.

ROYLE, in his "Illustrations of the Botany of the Himalayas," says:—"Ornamental as are all the known Primulaceæ, they are nowhere more so than in the coldest and most exposed of the Himalayan Peaks, and at a season when returning warmth has just begun to displace the scene of winter's desolation." This is certainly true of the pretty Himalayan species that have already been introduced to this country, and there remain still some species nearly as beautiful, which have not yet been seen alive in this country. Although originally found in very cold localities, most of the species are difficult of cultivation. It seems that it is not easy to find any substitute for the protection which these plants receive from the dense covering of snow which protects them throughout the winter in their native places of growth. *Primula denticulata*, introduced in 1805, appears to have been lost sight of for many years until re-introduced in 1842. *P. Stuartii* was cultivated by Wallich in 1824, but is mentioned as a novelty in England in 1845.

The following rough list, with a key to some of the species, has been prepared principally from notes made many years ago, and away from the herbarium at Kew:—

SECTION I.—*Armerina* (Lindl. in Bot. Reg., xix., t. 31).

Leaflets of the involucre extended downwards into a sheath, as in some species of the *Armerias* (Sea Pinks).

1. *Primula rosea* (Royle Ill., t. 76, l. 1; GARDEN, Vol. XVI., p. 12).—Leaves lanceolate, acute, glabrous on each side, shortly petioled. Calyx tubulose; the divisions about half the length of the tube of the corolla, the lobes of which are emarginate. Scape four to five times longer than the leaves. Flower pretty rose colour. Now abundant in English gardens. Raised from seed procured from Cashmere by Mr. Elwes. Quite hardy; stood the last winter in exposed situations. Found at Kedar-Kanta; also in Cashmere, and at the top of the Hungarung Ghaut (15,000 ft. to 16,000 ft.), in flower in August.

2. *P. elegans* (D.C.).—Leaves oblanceolate with a winged petiole, enlarged at the base, quite glabrous; scape scarcely twice as long as the leaves, but with few flowers; divisions of the calyx shorter than the tube of the corolla. Flowers large, lilac-coloured, paler in the throat; collected by Jacquemont in the lofty mountains of Cashmere.

3. *P. elliptica* (Royle, Ill., t. 76, 2).—Leaves elliptic, serrated, tapering into very long petioles. Scape two to three times longer than the leaves, few flowered. Leaflets of the involucre about as long as the pedicels. Divisions of the calyx one-third shorter than the tube of the corolla, which is straight, and not enlarged at the naked mouth. Flowers violet coloured, yellowish at the mouth. Found in the loftiest and most exposed mountains of Cashmere.

4. *P. involucrata* (Wall., Lindl., Bot. Reg., 1846. t. 31; Fl. d. serres x., t. 1023).—Almost bulbous, leaves ovate oblong, obtuse, glabrous, attenuated into a long petiole, almost entire. Scape two to three times longer than the leaves. Leaflets of the involucre oval, about as long as the pedicel. Calyx tube five ribbed; divisions shorter than the tube of the corolla, triangular, fringed on the margins. Found on the Roopen Ghaut in June at 11,500 ft. above the sea, the flowers varying in colour from pure white to a slight purple, and sometimes rose colour. Flowered at Chiswick from March to May, 1846, sweet-scented. Probably the same as *P. sibirica*, which is described as having purple-coloured flowers.

5. *P. Munroi* (Lindl. Bot. Reg., 1847, t. 15; Paxton Fl. Gard. 11, 469 and 405).—This is probably only worthy of being considered a variety of the preceding, with the flowers much larger, the leaves slightly cordate, and the tube of the calyx gradually narrowed into the pedicel, instead of being contracted just above the base, and then bulging out. Deliciously fragrant. Flowered at Chiswick March to May, 1847. Now common in England. Found at very great elevations in the Roopen Pass, flowering in June.

In none of the following sections are the leaflets of the involucre extended downwards.

SECTION II.—*Primulastrum* (Duby). Calyx generally loose and expanded. Our common Primrose and Polyanthus, the Chinese Primrose, and the pretty Japanese *P. cortusoides* belong to this section.

6. *P. petiolaris* (Wall. = *P. nana*, Wall. = *P. tridentata*, Don).—Leaves smooth on both sides. Flowers solitary, or one to three in an almost sessile umbel, blue or rose-coloured (according to Don). Lobes of corolla not bifid; throat naked. Found in Himalayas, below rocks, just above the limit of forest in June.

7. *P. mollis* (Hook., Bot. Mag., t. 4798.).—Leaves and whole plant covered with soft pubescence. Flowers in whorls, brick red. Lobes of the corolla bifid, with five scales in the mouth of the tube. Flowered in England in April, 1854, and this year in the Regent's Park garden in May and June, but still very rare.

SECTION III.—*Sphondylia* (Duby). Lower leaflets of the involucre large, similar to the leaves in shape. Divisions of calyx two to four times shorter than the tube of the corolla. Flowers in whorls. The well-known and pretty Abyssinian Primrose (*P. verticillata*) is a good type of this section.

8. *P. prolifera* (Wall. in "Asiatic Researches," xiii., p. 372).—Leaves quite smooth. Scape very long. Flowers yellow, sweet-scented. Tube of the corolla ten-striated, contracted at the mouth, with five small two-lobed tubercles. Found in the mountains of Silhet.

9. *P. floribunda* (Wall., Tent. Fl., Nepal, t. 33).—Leaves more or less hairy underneath. Plants 4 in. to 8 in. high. Flowers numerous, yellow, fragrant, very small. Tube of corolla hairy on the outside, naked in the mouth. A very variable plant. Found in moist spots on the sides of hills between Mussoorie and Simla, at from 4000 ft. to 5000 ft., in flower in May.

Neither of these two last species are likely to be hardy in this country.

SECTION IV.—*Arthritica* (Duby). Leaflets of the involucre considerably smaller than in the preceding section, and in some species very soon falling off; hence the name of the section. Flowers in whorls.

10. *P. purpurea* (Royle, Ill., t. 77).—Leaves oblong-lanceolate, farinose below. Leaflets of involucre sometimes as long as the pedicels. Divisions of calyx shorter than the much-dilated tube of the corolla, the throat of which is naked, and the lobes obtuse, not at all emarginate. Flowers dark purple, without any yellow in the mouth. Found in the valley of the Jumna at from 10,000 ft. to 11,000 ft.; Tibet, at from 14,000 ft. to 17,000 ft., and in some other localities in the Western Himalayas.

De Candolle places No. 13 and 19 in this section.

SECTION V.—*Aleuritia* (Duby).—Most of the species have the leaves more or less covered with a white or yellow mealy, farina-like substance. Hence the name.

SUB-SECTION 1.—Leaflets of the involucre smaller than in section *Sphondylia*. Flowers numerous, in heads. Pedicels frequently 1 in. to 1½ in. long.

11. *P. reticulata* (Wall. = *P. altissima*, Don).—Leaves quite smooth. Scape, 1½ ft. to 2 ft. long. Outer leaflets of involucre rather broad, lanceolate, and three-toothed at the top, equalling, or rather longer than the pedicels, which are 1 in. to 1½ in. long, the outer ones nodding. Calyx five-angled. Tube of corolla naked. Flowers yellow (Wallich); rosy purple (Don). Found at Gossain Than, in Nepal.

12. *P. speciosa* (Don).—Leaves cordate at base, with long, winged petioles. Outer leaflets of involucre lanceolate, acuminate, three or four times shorter than the pedicels. Calyx tube campanulate, not angled, with obtuse teeth. Flowers red or deep blue purple. Found in same localities as the preceding, which, according to Don, it very much resembles.

13. *P. Stuartii* (Wall.; Bot. Mag., t. 4356).—Leaves, 10 in. to 11 in. long, shining above, covered below with a yellowish mealy farina, "the grains of which (according to Dr. Balfour) are supported on short cellular prolongations." Outer leaflets of involucre ½ in. to ¾ in. long, shorter than the pedicels, which are upwards of 1 in. in length. Calyx covered with farina, twice as short as the corolla, the lobes of which are indented and covered with minute headed hairs. Flowers lively yellow. Collected at Gossain Than, by Wallich. Found very abundantly on Changseil and the Roopen Ghaut, flower

PRIMULA CAPITATA.

ing in June, and bearing ripe seed in September. Flowered at Edinburgh in 1847, from seed sent home by the late Sir James Hope Grant.

14. *P. sikkimensis* (Hook. in Bot. Mag., t. 4597).—Leaves not farinose. Scape 1 ft. to 2 ft. high, pale green. Involucral leaflets slightly farinose, erect, about half the length of the pedicels. Calyx as long as the tube of the corolla, the lobes of which are roundish and emarginate. Flowers lemon-yellow. Found "covering acres with a yellow carpet in May and June at elevations of from 12,000 ft. to 17,000 ft., in Eastern Himalayas" (Hooker). Flowered at Kew in May, 1851, at present abundant in England. There is occasionally a second whorl. Specimens have been seen with thirty to forty flowers on slender drooping pedicels.

SUB-SECTION 2.—Leaflets of the involucre extremely short. Flowers in dense, many-flowered heads, margin of leaves revolute.

P. denticulata (Smith, Exot. Bot., t. 114; Bot. Reg., 1842, t. 47; Bot. Mag., t. 3959; Wight's Icones, 2000).—Leaves generally appearing after the flowers, sometimes hairy, sometimes farinose on one or on both sides. Leaflets of the involucre are sometimes three-toothed at the top. Teeth of the calyx somewhat glandular. Pedicels short. Widely spread in the Himalayas at various elevations. Very common now in England. There is a variety of this called *P. purpurea* which is certainly quite different from *P. purpurea* of Royle. There is occasionally a second umbel.

P. cachemiriana.—At present a garden name. Very close to the preceding, the leaves appearing however with the flowers, covered with a very dense yellow farina below, and sometimes on both sides. Pedicels very short. Flowers rich purple colour above with yellow centres. Mr. Ware, of Tottenham, considers this to be a variety of the preceding. Quite hardy; stood out the last winter without any protection. Is now (November) in flower in my cool greenhouse.

17. *P. capitata* (Hook. in Bot. Mag., t. 4550; Fl. d. serres vi., t. 618).—Leaves oblong-lanceolate, farinose below and sometimes above. Flowers almost, if not quite, sessile, in very dense heads sometimes 2 in. across, deep lavender blue above, paler beneath. Tube of corolla somewhat transversely wrinkled inside. Flowered at Kew in 1850 from seed collected by Sir J. D. Hooker, in June 1849, at 10,000 ft. above the sea at Sikkim; again at Kew in July, 1878, in great perfection from seed sent by Mr. Elwes.

I think it is probable that the three preceding species are all forms of *P. denticulata*.

The accompanying drawing was made from a plant which flowered at Kew during the present year.

18. *P. erosa* (Wall).—Leaves altogether glabrous. Pedicels longer than in any of the three preceding species, radiating, four to five times longer than the leaflets of the involucre. Lobes of the corolla obtuse. Flowers lilac-coloured, paler in the centre. This has been generally considered to be a form of *P. denticulata*, but Regel says it is quite distinct. Found in Kumaon.

SUB-SECTION 3.—Flowers few in a terminal umbel. Plants not very dwarf.

19. *P. macrophylla* (Don).—Leaves elliptic, oblong, glabrous above, farinose below. Involucre four-flowered, with the leaflets four times as long as the pedicels. Teeth of calyx very blunt, keeled, about as long as the tube of the corolla, the lobes of which are orbiculate, scarcely emarginate. Flowers a pale lilac colour. Found in Nepal. No specific locality given.

20. *P. obtusifolia* (Royle Ill., t. 77).—Leaves very blunt obovate, farinose below. Involucre five-flowered, with the leaflets about as long as the pedicels. Teeth of calyx linear subulate, two or three times shorter than the tube of the corolla, which is enlarged at the mouth, with the lobes obtuse and not emarginate. Flowers lilac-coloured with a yellow eye. Found at Lippa in Koonawar, and at the top of the Roopen Pass in June.

21. *P. rotundifolia* (Wall).—Leaves about 1 in. or 1½ in. long. The whole plant sometimes covered with farina. Sometimes the leaves are glabrous above, with very narrow petioles often 3 in. to 5 in. long. Scape slender, 8 in. to 10 in. long. Involucre two to eight-flowered, with the leaflets nearly as long as the pubescent pedicel. Teeth of calyx linear-lanceolate, three to four times shorter than the tubes of the corolla, which is enlarged towards the mouth, and surrounded there with a raised ring. Lobes of the corolla blunt and indented. Flowers large, purple. Found at Gossain Than, and in deep valleys between Almorah and Mussooree.

SUB-SECTION 4.—Plants extremely dwarf and few flowered.

22. *P. pusilla* (Wall=Androsace primuloides, Don).—Leaves not 1 in. long, toothed, hairy, scape 2 in. long, with about three nearly ses-

sile, deep purple flowers. Tube of the corolla completely closed with a bunch of milk-white hairs. Found at Gossain Than, in Nepal, and by Sir J. D. Hooker in Sikkim, at 13,000 ft. to 15,000 ft. above the sea.

23. *P. minutissima* (Jacquemont).—Plant about ½ in. high. Leaves farinose beneath, hairy, with glandular hairs above. Scape farinose, shorter than the leaves. Tube of the corolla not hairy inside but glandular. Flowers rose coloured, almost sessile. Found at very great heights in some of the most lofty mountains in the Himalayas, flowering June to August.

24. *P. uniflora* (Hooker).—Plant 3 in. to 6 in. high; leaves very small. Scape bearing one large flower. Found in Sikkim at 15,000 ft. above sea.

25. *P. Stracheyi* (Hooker).—Scape bearing one large flower arising from the creeping prostrate stems.

The following are known only by name: *P. spatulata* (Royle) *P. involucreata* (Royle, not of Lindley), *P. nana* (Royle, not of Wallich). W. M.

GARDENING FOR THE WEEK.

Stove.

Fermenting Material.—Beds of this in stoves or elsewhere above pipes should not be too shallow. Several times, in taking charge of houses where pipes under a bed of this kind existed, I have had them removed, so as to give more depth to the bed. The gain thus effected is that the larger body of matter in this way admissible continues much longer without renewal to exert beneficial influences upon the plants, and it also helps the pipes to warm the house, for which purpose, if there were no other advantages, the introduction of a substantial body of fermenting matter, especially at this time of the year, when the greatest expenditure in fire-heat is necessary, effects a saving in this direction. Where clean Oak or Beech leaves are to be had, and the pit is sufficient to admit of a depth of 3 ft. or 4 ft., they will keep up a brisk heat for a considerable time, though not equal in this respect to that from good tan, which so far is preferable. In all cases where this last material is used, I should advise its being employed in as fresh a state as possible; where used immediately it is done with by the tanners, before it has had time to ferment, it lasts proportionately longer, and is clear from worms, which have such an objectionable disposition to get into the pots of plants, even when merely standing upon the surface of the beds. It is much better to get material of this kind in at once than later in the season. Advantage should be taken, when the old fermenting matter is got out, to thoroughly clean the house inside, both woodwork and glass, as well as lime-washing all the brickwork, by which means there is not only a decided gain in appearance, but the destruction of woodlice, cockroaches, ants, and other vermin, that increase fast where heat is employed, is effected, as well as considerable benefit to the plants, from the freer admission of light through clean glass than when it is coated with the slimy conferva-like matter that always makes its appearance where there is a moist atmosphere accompanied by a high temperature.

Stove Climbers.—Where these are planted out, consisting of such things as Aristolochias, Allamandas, the twining Clerodendrons, Ipomoeas, Thunbergias, Passifloras, and any others of like character, especially that have a strong, vigorous growing habit which necessitates their being cut closely in at the winter pruning, it will be well now to let the soil in which the roots are placed get as dry as the plants will bear without injury, as when the roots are thus brought into a dormant condition, there is much less disposition to bleed in plants that are liable to a loss of sap in this way, and which, wherever it occurs, has so far an exhausting influence as to cause them to break proportionately weaker with the extent to which the bleeding takes place.

Stephanotis floribunda.—The good of growing several large plants of this climber in pots is, that they admit of being moved about from one house to another, so as to make growth and be rested at different times, with a view to being started to give a succession. Where plants exist that were forced early last winter, and afterwards made and matured their growth in good time through the summer, which would admit of their now having had a fair season of rest, they may at once be put into the warmest house, where they will directly push growth, which, if the wood has been well ripened, will show flower before the shoots have extended far, and by this means an early supply of this most useful flower can be had. From the considerable length of time which a good-sized specimen, even such as can be grown in a pot and trained to an ordinary trellis, will continue blooming, where there are several plants of this description at hand, they will keep up a succession until those that may be planted out in cooler quarters come in.

Forcing Pit.

The advantages attendant upon having a structure of this kind at command are at no time of the year so evident as during the next three months, as the temperature and condition of the atmosphere requisite for those hardy plants that are being forced into flower is in many cases different to those needed by the ordinary occupants of the stove at this season. In a structure of this description, a good body of fermenting matter is of great assistance, from the influence it exerts on the atmosphere, as also affording plunging material for those bulbous plants and other things that may require it.

Eucharis amazonica.—There is no particular season for the flowering of this plant, as with sufficient stock and the help of houses with different temperatures, it may be had almost continuously in bloom. Strong vigorous plants that have been well grown, and had a short rest, if now put into the forcing pit, and plunged in bottom-heat, will very soon throw up flowers. The best way to secure a continuous supply of these flowers is to vary the times of growth and rest with different portions of the stock, so as always to have at command some that are in a fit condition for introducing to a brisk temperature. For private establishments this will be much better than treating the plants to a more uniform season of growth and rest.

Lily of the Valley.—This plant is a general favourite; yet in private places it is frequently not near so well done as it might be, often through the use of home-grown roots, the cultivation of which has not been such as to impart the strength to them necessary to ensure a full crop of flowers; though, where a suitable position is chosen, and the little attention required is given, it may be grown as well as the fine roots so largely imported, the crowns of which, under fair treatment, will not one in a hundred fail to produce flowers. It is well in the case of home-grown roots to select the strongest in the same way that is practised with those imported, leaving the weaker portion for replanting until they have acquired strength sufficient. There is nothing gained by giving the crowns of this plant intended for forcing more pot-room than just sufficient to hold the roots without too much compression. Pots 5 in. or 6 in. in diameter are better than larger, as if the plants are wanted when in flower for decorative purposes, the small pots give facilities for them, standing where larger ones could not be admitted, and small examples are little inferior in effect. The roots, as soon as potted, may be at once placed in bottom-heat of from 70° to 75°, plunging the pots sufficiently deep to admit of 1 in. or 2 in. of material, such as old tan or leaf-mould, being put over them, which covering will help them to move much quicker. In the course of about a fortnight the crowns may be expected to have advanced sufficiently to admit of their being taken out, as if allowed to remain too long in this position they will become drawn. When taken from the bottom-heat, they should be stood in the body of the house or pit, and covered with two or three thicknesses of paper, such as will subdue the light, gradually removing the paper as they will bear full exposure to the light, for, like Hyacinths and plants of similar description, if the young growth, whilst in a blanched condition, is suddenly exposed to the light, its effects are injurious. Where a temperature of 65° to 70° can be kept up, the flowers will progress apace, and may be looked for being in for use in a month from the time the roots were put into heat. I give these details as they may be of use to many who have hitherto treated this plant in a way that used to be common, the results of which were often unsatisfactory.

Hyacinths, Narcissi, and Tulips.—These may now be introduced to the forcing pit or stove as soon as they have made enough root progress; but until in this condition, it is no use subjecting them to heat, as however strong the bulbs may be, unless they possess enough feeding fibres, the flowers will not come strong. It is not well to hurry plants of this description so early in the season as this, and as soon as the crowns have got gradually inured to bear light they should be placed sufficiently near the glass to prevent their leaves being drawn. Hyacinths and Narcissi are frequently seen with lengthened foliage, so weak as not to be able to support itself, and the flower stems similarly elongated; in this way they have not a pleasing appearance, to say nothing of the flowers under such conditions being very much sooner over than they should be.

Crocuses, Snowdrops, and Scillas.—The former of these has been long used in quantities for forcing, and the two latter are equally suitable and give variety, all coming on with less heat proportionate to their natural disposition in blooming early with a low temperature; but where Scillas are forced, strong stout roots should be used, the flowers produced by which will be found very different to those forthcoming from weaker examples.

Lilac.—This is undoubtedly one of the finest of all forced winter flowers, especially manageable in the size of the plants, where these

have been grown and properly prepared for forcing, as other shrubs more generally used for the purpose. It will bear more heat without in any way weakening or rendering the flowers liable to flag than any plant I ever forced; but to have the bloom white, such as the Continental growers produce, the plants must be darkened whilst being brought on into flower; it should be kept moist, the plants being freely syringed.

Such subjects as the double *Prunus* and *Deutzia gracilis* may also be placed in heat, and if plants are available that have been forced in previous years, particularly of the *Deutzia*, which, after flowering last season, were allowed to make growth in some heat, say a Vinery or Peach house at work, the growth will have been early matured, and they will bloom much better with little forcing than those that have made their growth in the open air. As this is one of the best and most useful of all forced shrubs, or, in fact, plants of any kind for winter flowering, it should be grown in sufficient quantity to keep up a succession until the spring. Rhododendrons, in most parts of the country, have set fewer flowers than I almost ever recollect to have seen, and the fine small examples, full of bloom-buds, will be more difficult to meet with this year than usual. If any of these are put into warmth so early as this, it should only be the kinds that bloom naturally early and too soon in the open air to escape frost.—T. BAINES.

Flower Garden.

Auriculas.—Intense frost still continues, and although nothing can be done to the plants except to shelter them from frosts of undue severity, preparations may be made to facilitate work when it is pressing in spring. Compost may be prepared for surface dressing the plants when the time comes. As much as is likely to be required may be prepared and stored in a dry place. The compost for this purpose should be much richer than that required for potting purposes—say two parts good loam to one of rotted manure, with a small portion of leaf-mould, sharp sand, and pounded charcoal. Many growers are very careful to frequently turn over the compost which it is intended to use for potting purposes during the winter, but more harm may be done in this way than by allowing the heap to remain undisturbed. If the heap is wet or in a frozen state, I would not touch it, indeed, I never do so at any time. The loam is stacked up in a heap, so that the wet is thrown off, and never at any time is it not in good condition to use. I like to have the compost mixed and laid up in the shed about three months before using it. The labels are apt to be defaced by exposure, and it may be well now to see to renewing them.

Carnations and Picotees.—The same remarks apply to these as to Auriculas; all our plants are frozen, except the few that have been placed over a hotbed, and these have not been so comfortable as we could wish. I was at Mr. Dodwell's the other day, and he told me that he kept a lamp burning night and day in a cool house in which he keeps his store pots; his reason for this is to keep the frost out as much as possible, though it does not quite do so. When a thaw does come, there will, he says, be a much better opportunity to commence potting at the earliest possible moment. If the plants are not established early, so that they can begin to grow away slowly at first, there is no chance to get a good bloom in the current year. When the plants begin to throw up their flower stems, there is such a rapid drain upon the resources of the plants that unless they are well rooted failure is certain to be the result. No one would think of applying water to the roots while frost continues, and even if there should be a thaw it is best at such a time to err on the side of dryness. See that neither melted snow nor rain are allowed to find their way through the cracks of the glass, and so cause drip to fall on any of the plants. In the last line of my notes on Carnations (p. 512) last week, the word "free" should be substituted for "suffering."

Hollyhocks.—These need little attention at present; they are quite safe where planted out in cold frames. Those on shelves near the glass in a cool house, from which frost is excluded, will require water when they are dry, but the plants do not like much wet at this season.

Pansies in Pots.—These are also at rest. We plunged the pots this year in dry Cocoa-nut fibre refuse in preference to placing them on a stage. The plants were not so early established as they ought to have been for such an early winter. In all cases where an early bloom of any of these hardy flowers is required, it is very desirable to propagate the young stock early and pot the plants some time before there is any chance of severe frost.

Pansies, Pinks, and Carnations.—The hardy kinds of these and other plants in beds must just be left alone at present. Where they are well covered with snow they will be quite safe as long as they are in that state. It is when a thaw comes, and the beds are soaked with melted snow, to be again frozen, that there is

danger. Many plants that can stand bravely any amount of frost speedily succumb to alternations in the way of weather in our very changeable climate. Any protection that can be devised to shelter the beds from frost when the ground and plants are wet will be useful.—J. DOUGLAS.

Hardy Fruit.

A continuance of the present severe frosty weather will, as a matter of course, put a stop to all planting and renovating of borders; but there are other operations which, but for such weather, might never have attention at all. Amongst these are grubbing up old fruit trees, cutting out all the dead wood in orchard plantations, and otherwise thinning out the branches, particularly such as are crowded and intersect each other. All Moss or Lichen should also be rubbed off them, and if afterwards they can have a good splash over with newly-slaked lime and soot, this will prevent the Lichen from growing again for a long time to come, and so put an end to a convenient harbour for insects. Usually such orchards are on Grass, and, in the matter of manure, are left to take their chance, a circumstance more attributable to custom than to any real feeling that manure is not required, which it most certainly is, in order to ensure fine fruit. A good dressing of stable manure ought to be given every alternate year, and if this be scarce, soot and wood-ashes form a most excellent substitute, and should be applied now, in order that the winter rains may wash them down to the roots before growth commences. By thus annually devoting a few days' labour to old orchards, they might be made much more remunerative. If the sorts are not the best, and the trees are healthy, this can soon be remedied by grafting; and when pruning good kinds the shoots should be saved for grafts, and heeled in at the base of the trees till required in March. The trees that have to be grafted may be headed down at once. Cut off all ground suckers with a spade. Whilst the ground is hard through frost, let all wheeling of manure and soil on to the fruit quarters be done; also clear up all prunings, hedge-clippings, and vegetable refuse of every kind for burning, the ashes from which is a valuable fertiliser for any crop. Though it seems wrong to prune trees in frosty weather, I have never noted any ill effects from it; but I would recommend that only the commoner and hardier kinds be done, and this solely with the view of forwarding the work. Currants, Gooseberries, and Raspberries may all be done in such weather as that we are now experiencing without any risk of danger whatever. American blight is more than usually prevalent this year on both Apples and Pears, and in order to effectually cleanse the trees from it, much pains will have to be taken to first of all wash it off with hot soapy water, and then to paint over the affected parts with a strong solution (8 oz. to the gallon) of Gishurst Compound; or a strong solution of soft-soap water, and half a pint of paraffin oil added to 3 gallons of the solution, is equally effective. A greater quantity of the oil might prove fatal, but this amount we have proved to be both safe and a sure destroyer of the insect. Amongst all hardy fruits, Peaches and Cherries are the most subject to attacks of aphid early in summer, and, by way of prevention, these should always have a winter dressing of the solution just named. Cherries may have it as strong as recommended for American blight; but Peaches should have the Gishurst at but 4 oz. to the gallon of water. I believe that Gishurst is not always of the same strength; hence, to be safe, I prefer to use strong soapy water only as a dressing for Peaches. The walls as well as the trees require dressing, and these we do with soap-suds fresh from the laundry applied with the garden engine. Such an annual dressing, by preventing attacks of aphid, saves a large amount of labour and annoyance in the early summer months, when, through pressure of other work, it is difficult to find time to attend to them. As soon as the frost disappears, push to a close all arrears of draining, trenching, and forming fruit-tree borders, in order that the ground may get consolidated before planting the trees, which ought now to be delayed till February. See that recently-planted trees are securely staked, and that both these and all that require manurial aid should at once have a thick covering of the best manure at command.—W. W.

Extracts from my Diary.—December 15 to 20.

FLOWERS.—Putting a few Azaleas into heat. Looking over bedding plants, and pulling off all decayed leaves and blooms. Looking over Violets in frames, and picking off all dead leaves. Sponging Camellias and Stephanotis.

FRUIT.—Getting first batch of Strawberries (started in leaves in a frame) into Vinery to continue their growth. Looking over late Vines, and pulling off all decayed leaves and stalks to admit light. Covering up Cherries in tubs and pot Figs with a little dry straw for protection from frost. Mulching Plum border. Emptying Peach house of old border, and scrubbing paint with soft soap to kill insects. Putting fresh linings to Pine pit. Pruning Peach

trees in second house, and Figs on back wall. Cutting ties of Peach trees in cold houses. Painting Fig trees on back wall of Peach house with a solution of Gishurst Compound, soot, and clay. Preparing bottles for Grapes, and clearing out place in fruit room for storing them.

VEGETABLES.—Tying winter Cucumbers, and thinning the fruits. Wheeling manure on ground ready for digging in. Covering up Potatoes in store rooms with hay for protection from frost. Turning Mushroom manure to ferment. Shifting French Beans from pit where they have been raised to lighter house. Cutting Veitch's Self-protecting Broccoli ready for use; also Mushrooms. Getting in a little more Seakale into Mushroom house; also more Endive and Lettuces for blanching. Sowing Mustard and Cress.—R. G., *Burghley*.

THE FRUIT GARDEN.

PACKING PEACHES FOR MARKET.

UNDER the false impression that Peaches do not attain their full market value until they are quite ripe, eight out of ten private growers of this valuable but perishable fruit allow them to hang too long on the trees before they commence gathering, and are considerable losers thereby. As soon as a Peach has attained its full size and colour, although quite hard to the touch, it is in the best possible condition for sending to the fruiterer. Risk of injury in packing and travelling is then comparatively small; the gain of a single week in the case of early Peaches often makes a considerable difference in the price, and they arrive in a fit state for storing away in the vaults, to come out in their turn, instead of having to be thrown into the market immediately upon delivery. By way of illustration, I may state that it is by no means unusual for the Messrs. Webber to have from sixty to a hundred dozen of Peaches at one time in the month of July in their vaults gradually but surely ripening, and these are the fruit for which they pay the highest price to the growers, for the simple reason that they can hasten or retard them to suit the requirements of their trade. Every private gardener who is in the habit of sending large supplies to his employer's town residence, knows that it is not always safe to be without ripe Peaches fit for immediate use, and this fact soon teaches him that these over-ripe fruit when sent away at the eleventh hour are sold at a great loss to the grower and annoyance to the dealer, who is obliged to force them in a glutted market, instead of stowing them away for a few days to meet a good order which might enable him to give a much higher price. It is not for these men who have bought and paid for their experience that I am now writing, but they will bear me out in saying the state of ripeness is quite as important as the mode of packing.

I will now proceed to lay down a few rules to be observed by young beginners. Always have a good supply of dry Moss in store, the best and cheapest of all packing materials. If properly beaten and prepared it is soft, elastic, and never heats in the boxes. Be very careful in the use of bran, an excellent thing if pressed in very tight; but as it has a tendency to sink in bulk when shaken on the journey, the Peaches become loose, and, as a matter of course, separate from the packing and arrive in a bruised and worthless condition. Never use wadding (the worst of all packing materials) for soft perishable fruit, as it absorbs moisture, becomes very hard, and heats on the journey. Avoid using large boxes; 24 in. by 14 in., and 4 in. deep inside measure, is a suitable size for twenty to twenty-four fine fruit. Always have the lids in one piece, nail slightly, and cord one or more boxes together. Place the direction label, and one marked "Fruit, with care," on the top—"To be met at the terminus: this side up." I once heard of a porter who walked into a shop in the Centre Row, carrying a box with cards on the top and two sides. Puzzled by his instructions, he informed the fruiterer that he had given each of the cards a turn upwards on his journey from the station, and hoped he had succeeded in carrying out the sender's directions! Always gather in very close before the end of the week, and unless specially ordered, never send away later than Friday morning. Although Peaches may be sufficiently advanced for sending away, their hold is too firm to admit of their being plucked from the tree without injury by the pressure of the fingers; but if a piece of wadding be taken in the left hand, with which the Peach is firmly grasped, and a pair of finely-pointed scissors be used with the right it may be detached without being bruised. It should then be placed on a piece of silver paper 9 in. square, and laid in a shallow box or flat basket containing a good bed of Moss. When gathering—which should always be performed early in the morning—is finished, proceed to the packing-room and prepare the boxes by lining the sides and ends with paper, allowing the half of each sheet to hang over the sides for turning over the top when all is finished; then place a good layer of Moss evenly over the bottom, slightly tilt one end, and commence by folding the

fruit in the squares of paper on which they are resting. Shake a little loose Moss along the lower end of the box, and place the first Peach in one corner. Keep it in its place with the left hand, follow with more Moss and fruit, never withdrawing the left hand until the first row of four is finished; then form a division with more packing, and proceed until the box is full. Each Peach will then be resting in a soft nest of Moss—say an inch from the bottom, and about the same distance apart. Continue the introduction of packing until every fruit is quite firm in its place, with room for half an inch of Moss between the fruit and the lid. Owing to the lightness of the lid, a little judgment will be needed in placing the last layer, as safety in transit depends upon the degree of tightness secured by pressing down the lid; turn over the half-sheets of paper, nail slightly, and always cord well. When bran is used the boxes should be well lined with plenty of paper to turn over the top, to prevent it from working out. Always make a good bed, as many Peaches are spoiled by being placed too near the bottom; place all the Peaches on this bed in the position they are to occupy, keeping them half an inch from the sides, and an inch or more apart; then fill up with bran, and shake it down, but it will not be safe to rest satisfied with shaking only, as constant shaking on the railway soon reduces the bulk, and in nine cases out of ten where bran is used the Peaches work up to the top or one end, and the bran going in an opposite direction, loss and annoyance follow. An abundance of bran should be placed on the top, and be well worked down into the corners and between the fruit with the fingers, until every part is quite firm and a little higher than the sides of the box, so that an inexperienced person might think it too full, then fold over the paper and secure the lid with two small nails.

When more than one box is sent off always make first and second quality, place record of quantity and directions on the lid, never on the sides or ends. When large ripe Peaches have to be packed for private use immediately upon arrival, they should be gathered two or three days before they are wanted and placed upon squares of paper or hair sieves. Great care must be observed in moving them with pads of wadding in the hands, and an extra quantity of Moss should be placed under them in the boxes. The folding of these and all tender fruit is best performed on a sheet of wadding spread out upon the table, and they should be packed with the apex pointing upward towards the lid. Nectarines and Figs may be packed in shallower boxes and in exactly the same manner as Peaches, but on no account should Figs be packed in bran or wadding, as, owing to the moist nature of the fruit, they are liable to heat, independently of the danger of their coming in contact with and adhering to the fruit, from which it is hardly possible to detach them. Paper shavings of fine quality are very good, and, owing to the fact that they admit a certain quantity of air, decomposition in Figs, which must be well coloured before they are gathered, is not so likely to set in; but in good hands, with confidence in packing as in the performance of all delicate operations and a little practice, properly prepared Moss will be found the best and least costly medium for Grapes, Peaches, and Figs.—W. COLEMAN, *Erstnor*, in *Gardeners' Chronicle*.

LATE BLACK HAMBURGH GRAPES.

IN reference to this subject, "J. S. W." says (p. 458): "In order to have Black Hamburgs late, it is not desirable to start the Vines too soon; indeed, they should be kept back as late as possible, or till the buds break naturally, as used to be the practice when the construction of Vineries allowed us to take the Vines outside till the time came for starting them. But even in our modernly-constructed Vineries there need be no difficulty in this respect, for by keeping the ventilators open it is easy enough to prevent growth till May or later; and Black Hamburgs started at this season and pushed on in a moderate temperature, will ripen 'about' the beginning of October, which is about as good a season for ripening Grapes generally as we have, and the fruit will keep three months longer." These are "J. S. W.'s" exact words. I certainly find, on referring to p. 496, that I used the words "early in October" and "latter part of May," but these words make no material difference except in this, that "J. S. W." by vaguely saying "May or later" gives his Vines a longer period of rest, and therefore a shorter time in which to mature their fruit. Yet in support of his argument (p. 516) he sets aside the months of May, or maybe June, or some other month, and substitutes April in order to rectify himself, and would, I dare say, have your readers suppose that these five or six weeks (for which I contended) make but little difference in the end. My statement was that Vines reaching maturity in the beginning of October could not through the spring months be kept at rest till "May or later," and this I still maintain. To keep a Vine at rest for eight months, and leave it only four in which to perfect its fruit is simply, to say the least about it, contrary to all reason; nor would I recommend any one to try to do so, even as an experiment. For

myself I may say that I have this autumn seen in late Vineries in various quarters more immature Grapes than ripe ones, and I feel sure that such would not have been the case had the Vines been encouraged earlier by simply closing the houses sooner, and pushing them along a little brisker afterwards. Therefore, I trust that my remarks on maturing late Grapes will not be so readily dismissed from consideration as "J. S. W." assumes. Adverting to "J. S. W.'s" remarks on the extraordinary crops of Peaches and Nectarines produced annually in the houses here, I consider that already sufficient evidence has been adduced as to the fact, but as he still retains doubts, I trust he will be able to make the journey here which he proposes to do in July next, when I hope to have a greater surprise in store for him, for I have never had my trees in such good condition at this, their winter pruning, as they are now.
Sunbury Park.
THOS. COWBURN.

LARGE v. SMALL GRAPES.

URING the last few years a great change has taken place in regard to Grape culture; instead of the very early examples of new Grapes upon which some cultivators used to pride themselves, we have now generally adopted a system of growing late thick-skinned sorts, that are kept in good condition until Hamburgh and other early kinds are fit for the table, and in this respect we have, I think, stolen a march on our forefathers; for, an early Vinery in which the crop is ripe in May, will, under good management, last for years, whereas if the crop is required early in the new year, it cannot last long. Thus far I think, we are benefited by the introduction of Lady Downes, Alicante, and similar sorts, and these, too, seem likely to be displaced by Gros Colmar, in comparison with which small berried varieties are lost, even if grown under exactly similar conditions. In this however, we exchange quality for quantity, a circumstance to be regretted, as many of the finest flavoured Grapes are likely to be lost entirely or only grown by connoisseurs, who are proof against the prevailing taste for large berries. There can be no doubt that if Grapes were judged the same as Melons, by flavour, the Frontignans, Royal Muscadine, West's St. Peter's, and sorts that were popular twenty years ago, would beat all the new kinds now so largely grown, and yet both Melons and Grapes are supposed to be grown to eat. Yet one is judged as if it were solely for ornament, and the other for eatable qualities alone. In nine cases out of ten, the largest best looking Melons get no recognition at all. But that is not the case with Grapes, large berries and heavy bunches have caught the eye of the judges at fruit shows, and of writers for the gardening press, until the remark "what fine Grapes they had at such-and-such a place," comes to be considered of more importance than "what good Grapes we tasted at some other place." In this respect, all of us influence one another, and at present the prevailing fancy is all in favour of large bunches and larger berries, and few of the high flavoured sorts, if we exclude Muscats, are able to hold their own against large coarse growing sorts. Doubtless, a reaction will come sooner or later as popular opinion generally rushes to extremes; still I hold that it would be an interesting and instructive lesson and variation, if at fruit shows we had special classes set apart for high flavoured kinds; such a classification would simplify the duties of the judges and tend to indicate the special claims of each particular kind of Grape exhibited. Raisers of new kinds always look to improving, or enlarging, the points most prized in the subject operated on; therefore, unless some such plan as has just been stated is carried out, quantity may eventually supersede quality to an extent that may prove anything but an advantage if pushed to extremes.
J. GROOM.

Linton.

Norwich Prolific Nut.—The history of this new Nut is thus given to us (*Florist*) by Messrs. Ewing & Co., of Norwich, in whose nursery it was raised: "The original plant is from fifteen to twenty years old. It came up promiscuously in the nursery amongst other stock, and was left out of curiosity. It still stands where it first grew, and produces freely every year, and has done so for some years past. The fruit is quite distinct from and much larger than that of any other variety we grow. The shell is almost as thin as that of the Cosford, and is well filled, the kernel being of good flavour. We think it will also turn out to be a good keeping sort. We do not observe that it often produces fruit in clusters, the Nuts being usually two or three only on a stalk, and most commonly two. It is, however, a very prolific sort, and plants not more than 2 ft. high frequently produce fruit of very large size." The young wood of this variety of Nut has a thick covering of hairs, and the leaf-stalks and leaves are similarly clothed. The leaf is roundish, deeply cordate at the base, with shallow angular lobes, and coarse serratures. The Nuts are short, plump, nearly square in outline, $2\frac{1}{2}$ in. in circumference, flattish at the base. The kernels, which are full and of

excellent flavour, are enveloped when ripe in a whitey-brown skin, enclosed by a somewhat thin and light brown shell. This new variety seems to come nearest to the Cosford Nut, in the characters of the short husk and somewhat tender shell, but is of different shape, being squarish rather than oblong, and the husk in some examples is quite as long as the Nut.

THE INDOOR GARDEN.

LILIES UNDER GLASS.

In the cultivation of Lilies for greenhouse decoration, it frequently happens that they are left much too long without repotting, an operation that should be performed immediately after the fall of the leaves, as then they can be handled and the balls reduced with safety, which cannot be done later on when the large fleshy roots have pushed out from the bulbs, they being of an exceedingly tender and short brittle nature. By giving these fresh soil early, they soon thread their way amongst it, and from the fresh food they find there add considerably to the strength of the young stems as they emerge from the scales. In preparing the pots the drainage is a very important matter, as owing to the copious supplies of water Lilies require when growing, it is very necessary that provision should be made to admit of its passing freely away. This being the case, crocks should not be spared, and to ensure these being kept clear and open, it is a good plan to scatter a little Moss over them, and on this a sprinkling of soot, which answers the double purpose of a stimulant at a time when it is most needed, and helps to keep out worms, these having a very strong objection to coming in contact with it, even though it may have lain and lost much of its properties by the washing it there undergoes. Not only do worms do injury by the perforations they make throughout the ball, but they initiate themselves between the scales of the bulbs, and I have seen numbers of *L. auratum* destroyed by them. Whether they devour any of the more fleshy part I am unable to say, but certain it is that when they get amongst them the bulbs soon begin to decay.

This may in a great measure be prevented by covering them with sharp sand, which keeps the fine soil from coming in immediate contact with them, and preserves them in a clean healthy condition.

The great thing in the successful pot culture of *L. auratum* is not to give it too much root room, as it will invariably be found that the best plants are those that are somewhat restricted. For single bulbs deep 7-in. pots are quite large enough, and these are useful sizes for general purposes, and come handy for dropping in on greenhouse stages, where a few heads of this magnificent Lily in bloom have a most telling effect. The flowers of the different varieties of *L. lancifolium*, being much smaller, make a better display when several are massed together, and growing several of one kind together in large pots so as to make fine specimens, having from five to ten stems staked properly out. To produce such plants as these it is necessary to select the largest and strongest bulbs to be potted together, that the growth may be uniform. In placing these in the pots they should be distributed regularly, having first laid in a little rough soil over the crocks, and the bulbs being then in the proper position, the next thing is to fill in the spaces between with the same kind of material, using enough to just cover over the tops, so as to leave plenty of room for top dressing. It has been said that stem roots are no help to the plants and should not be encouraged, but Nature never makes mistakes, and it is therefore certain that they would not be there were they not for a purpose which is to help to sustain and carry out the flowers, the massiveness of which shows how much such assistance is needed.

Although Lilies will grow and succeed fairly well in almost any soil, I prefer a mixture of fibrous peat and loam in about equal pro-

portions, which mixture cannot well be used too coarse, as the main roots of Lilies, being large and quill-like, are able to ramify in it in a more easy manner. The practice of using manure for bulbs of this kind in pots is not to be commended, as there is always a risk that it may induce rot, and what assistance they require can always be given in a liquid form, when there are plenty of roots to take it up, and the necessary amount of foliage to turn it to proper account. If the soil at the time of potting is moist and in the condition it should be, no water will be required for some time, and to obviate its being needed to as late a period as possible, the pots should be placed on a damp floor in a cold frame, instead of in positions where they will be exposed to dry currents of air. In the former situation the growth they make is gradual and strong, to prevent the drawing up of which they must have plenty of light by being placed near the glass till the time of year arrives when they will be safe in the open, and a portion for late flowering may be left out in any sheltered part where they can have full sun, and be secure from cold cutting winds. There they can remain snugly till the autumn; when brought into the greenhouse or conservatory they will soon expand their buds, and remain a long time in full beauty. As soon as the blooms fade the plants should be exposed again so as to ensure a thorough ripening, to aid in bringing about which it is important that they then be kept moderately dry at the roots.

S. D.

CYTISUS RACEMOSUS IN SMALL POTS.

This fine old greenhouse plant is nowhere seen so well grown, or in such good condition, as in Covent Garden, and that in remarkably small pots. Charming flowered bushes of it, from 18 in. to 2 ft. in height, and as much through, may be seen in pots never larger than 6 in. or 7 in. in diameter, in thousands in Covent Garden in March and April. Owing to its hardy character, it is one of the very best of decorative plants, and therefore it is well suited for all furnishing purposes. Being so hardy, it is also a good plant for the amateur cultivator who has only a limited supply of heating power in his greenhouse, as a slight frost will not injure it. A temperature of about 40° is quite sufficient for it in winter, indeed better than a higher one.

The best time to propagate this plant I have generally found to be the month of September, by which time the summer growth has become moderately firm; if an old rough specimen is available, it

will, at this season, furnish a good supply of cuttings. These should be taken off, about 1½ in. in length, with a sharp knife. Make a clean cut below the lowest joint and remove the leaves about ½ in. up the stem. The soil used should be half peat and loam, and plenty of silver sand; well drain the pots (6-in. ones are the best), and fill them moderately firm with soil to within ½ in. of the rim; place on this a layer of silver sand, then insert the cuttings moderately thick, and give water with a roset-pot to settle the sand round them; then place them in a frame in a shady position on a good thick coating of coal ashes. Keep the sashes tolerably close for a time, merely giving a little air every morning to dispel damp. Be sure to pick off all decayed foliage, and keep the sand in the pots just moist. Amateurs will find this *Cytisus* more difficult to strike than *Pelargonium*, but the pleasure attending success will be proportionately greater.

After the cuttings have been in a few weeks they will, generally speaking, have formed a callus. This can be known by their having the appearance of starting into growth, and when that happens they may be removed to a shelf near the glass in the greenhouse. Be sure the soil in the pots at this stage is not allowed to become dry, for if so, they will certainly die. When rooted pot them off carefully into small thumb pots, using similar mould to that just alluded to, replace them on the greenhouse shelf, and if the pots could be set in a little Cocoa-nut fibre so much the better; or if a pit is available, with means of excluding severe frost, that is the best of all places for them, as they delight in all stages of their existence in

Anthoecris viscosa A New Holland Shrub.

a cool moist atmosphere. When the soil becomes moderately dry give it a good soaking of water, and afterwards keep them through the winter just fairly moist at the root, and that is all. By the month of February the points of the shoots should be pinched out, an operation which will cause them to break out and become bushy. They may now be shifted on into 3-in. pots, and encouraged to grow freely, giving them abundance of air on all favourable occasions.

When the month of May arrives, and all danger from frost is over, re-pot them into 4-in. or 5-in. pots, according to their strength, using rather more loam than before, and potting firmly; now select a place out-of-doors on which to set them with a good hard bottom, so that worms cannot work into the pots; place the plants thereon in the form of a bed of convenient width for watering, &c. Be sure not to crowd the plants together, but allow sufficient room for sun and air to get freely amongst them. The spaces between the pots should be filled up with coal ashes or Cocoa-nut fibre. This will obviate the excessive use of the watering-pot. A piece of board round the edge of the bed will keep all neatly in their places. As the plants progress in growth, keep them well pinched in, so as to form compact bushes, and in hot weather syringe them freely night and morning, and be sure that they are never dry at the root. This is not a plant that requires much manure, but I have found a little soot-water useful occasionally; it causes the foliage to assume a good dark green colour. By the end of August they should be ready for their final repotting into the pots in which they are to bloom, using sizes not larger than 6 in. or 7 in. About a week after they are potted they should receive their final pinching, as if this operation is deferred to a later date they do not produce such fine flowers in the spring. Keep them out-of-doors until there is danger of their being hurt by frost, and then remove to their winter quarters, which may be either to a pit or to the greenhouse, as may be convenient; if to the latter give them the coldest end.

There will now be little to be done beyond attention to watering and ventilation until the spring, when they may be aided by a little weak manure-water, and freely syringed until the flowers show colour. By the month of March it will be found, if these directions have been adhered to, that the point of every shoot will produce a flower spike, and that the whole plant will shortly be a blaze of golden blossoms, fully rewarding the cultivator for his labour. This plant is not so subject to insects of any kind, and it can be grown to the greatest perfection in a small state without either stake or tie.

HENRY BAILEY.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Siebold's Primrose.—Mr. Gumbleton informs us that this Primrose, commonly and unfortunately called *Primula cortusoides amena*, is breaking more and more into beautiful varieties. He has about thirty good kinds, lovely plants for pots. Although quite hardy, their flowers often suffer in the open air, and it is not every soil or situation that allows of their fine growth out-of-doors.

Hybrid Ivy-leaved Pelargonium St. George.—This very beautiful variety of hybrid Ivy-leaved Pelargonium was raised by Mr. J. George, of Putney Heath, who is also well known as a raiser of choice novelties of other races of the Pelargonium family. It is, according to the *Florist*, in which there is this month a coloured plate of it, the result of a cross between *P. peltatum elegans* and a zonal variety, and is a most attractive plant, being of free habit, and producing abundantly ample trusses of bright salmon-red flowers. Mr. George states that he has for some years been engaged in attempting to improve the Ivy-leaved Pelargoniums by crossing them with the zonals. In this attempt he has made the Ivy-leaved sorts the seed-bearers, his object being to retain their very distinct habit and to combine therewith the larger trusses and more brilliant colours of the zonals; but he has found the process a slow one, inasmuch as the plants of hybrid race will not perfect their seeds. The hybrid Ivy-leaved Pelargoniums are all of a trailing habit, but some are much stronger growers than others. Thus the varieties called *Nemesis*, *Gem*, and *Argus* are best adapted for vases or basketwork; while *St. George*, *Mrs. J. George*, *Dialium*, and *Progress*, being stronger growers, are best suited for pillar or trellis-work. These hybrids are in every way superior to the true Ivy-leaved types, the colours being so much brighter and more varied, and the trusses very much finer and bolder. Of the distinctness, beauty, and utility of these novel sorts there can be no question.

Browallia elata.—I have grown this plant for some years, and agree with your correspondent (p. 504) that it is a matter of surprise that its value is so little recognised. I sow it in an ordinary greenhouse about March and April, and it germinates quickly without bottom-heat. As soon as the seedlings can be handled, I prick

them off into thumb-pots, and shift afterwards into 5-in. ones. With a little stopping they make compact, bushy plants about 1 ft. high, and bloom most abundantly and continuously. I find that they require plenty of water during the summer months. I have not yet tried them for winter blooming, but I have no doubt they would be a great acquisition late in autumn. The blue variety is the most valuable, and, according to my experience, the most compact in habit; but a bunch of the blue and white mixed makes a charming bouquet and lasts a long time in a cut state.—W. J. T., *Brixton*.

—I have grown both the white and blue varieties of *Browallia* in quantity for several years, and by following as nearly as possible the system of cultivation described (p. 504) by your correspondent, have found them most useful, either for indoor decoration or for furnishing cut flowers, as when grown under glass they are useful in bouquets, forming as they do an excellent substitute for *Forget-me-nots*. I have generally planted some of the surplus stock out-of-doors at bedding-out time, and have found the blue variety to make an effective bed; but the white sort is scarcely white enough in the open air for bedding purposes, but under glass its purity is greatly increased. Both plants are well adapted for amateurs, as they may be grown out-of-doors during summer, and will flower freely in any warm greenhouse when taken indoors in autumn and winter.—J. GROOM.

Gardenias Planted out.—These are planted out near the glass in a warm pit at Goodwood. The result, compared with pot culture, is better health, freer growth, numerous and finer flowers, and leaves that sometimes more resemble those of a *Magnolia* than a *Gardenia*.—V.

Ramondia pyrenaica.—This does remarkably well in the Cambridge Botanic Gardens as a cold greenhouse plant. Growing in a 5 in. pot, it has fine large crowns, and is making offsets. When in flower it must have been extremely handsome, judging from the number of its seed-pods.—L.

Gesneras in Rooms.—These and their allies do not receive their due meed of attention as decorative subjects for rooms, &c. Any one having the advantage of a little warmth can easily grow them into little specimens a foot or eighteen inches high, when they may be removed to an ordinary sitting-room, where they will remain in undiminished beauty for several weeks, even in winter; they will not, however, open their bloom buds. Similarly, *Gloxinias*, with a flower or two open, will, in the summer time, continue to expand blossom after blossom in the drawing-room quite as well as in the stove, and the flowers will last longer in perfection.—GREENWOOD P.M.

Hibiscuses.—I was in error in the statement (p. 486) that *Terminalis elegantissima* of gardens is the juvenile state of *Hibiscus liliiflorus*. What it really is is uncertain, as the flowers are unknown, but my statement was based on an incorrectly named specimen.—W. B. HEMSLEY.

Nelumbium speciosum.—I am told that the Chinese grow the rosy-flowered *Nelumbium speciosum* in vases before their temples wherever they may be located in the East. This reminds me that there are two other of these Sacred Lotus plants which may be grown in tubs or tanks in a warm and sheltered part of any English garden during the summer months. These are *N. aspericaule*, a hardier seedling variety of *N. speciosum*, and the "Golden Swamp Lily" (*N. luteum*), of Texas and the Southern States of North America. Lotus pools are a great feature in the landscapes of Japan, as illustrated by a picture in the last Royal Academy exhibition; but by taking advantage of these hardier varieties there is no reason why there should not be Lotus pools in every warm and sunny English garden.—F. W. B.

Eichornia (Pontederia) azurea.—It is very rarely indeed we have to illustrate an aquatic plant of any great beauty, but *Eichornia azurea* is one of the most charming plants which we have ever seen. It was introduced to the Botanic Gardens, Regent's Park, and the whole of this autumn, and until recently, has been one of the most charming plants imaginable. Unlike other plants of the same family, it flowers very freely, the delicate purple spikes rising frequently among the large shining leaves. The shoots run freely over the surface of all the water in a stove tank of the Victoria House. With the exception of the Water Lilies themselves, we know of no more valuable plant; and then, being quite distinct, and a much freer bloomer than the others, it is still more desirable for general culture. Although we saw it in the Victoria House, at Regent's Park, its size is such that it could probably be grown easily in a tank in a warm house. All botanic gardens should possess it. The flowers have a bright little yellow eye, which gives them a pretty aspect when closely examined; but the distant effect is even more remarkable. We hope to give a coloured figure of it soon, and thereby show more effectually what the plant really is.

A Beautiful Stove Water-plant, *Eichornia (Pontederia) azurea*.

TREES, SHRUBS, AND WOODLANDS.

SHELTERS FROM COLD WINDS.

COLD affects plants much in the same way as it does animals; in the case of both it is not alone the extent of cold as shown by the depression of the thermometer, that is felt, but the unchecked current of wind when there is nothing to break or intercept its force. This people know from personal experience, when exposed in an open situation to a brisk wind, with the thermometer showing say 15° of frost—that amount often feels much colder than when the instrument shows 25°, and it is quite calm. Few who have anything to do with gardening matters are unaware of this, yet both trees and shrubs of a character unable to bear severe cold in exposed situations are often planted there. It generally happens in cold winters that quantities of plants, often highly prized by their owners, are lost from want of a little timely protection being given, that in itself might do little to ward off actual frost, but which would yet save them from death or injury by shielding them from the wind. I am not so much alluding to low growing plants that do not rise much above the ground, as to shrubs and young trees that require something higher to shield them when planted in open places. In the case of young trees in gardens and pleasure grounds that are so circumstanced, it is always labour well spent to do something to give them a little shelter; but in doing this it is well to be careful not to do harm instead of good. I have often seen, when mats insecurely tied to stakes and poles or other materials of a like description were used, that the means intended to protect did more injury than good by chafing against the branches which they were meant to shelter.

I have found light straw shutters well suited to the purpose; they are made by enclosing a thin layer of clean straight Wheat straw, not more than half an inch in thickness, between ordinary large wire Pea hurdles, bound tightly together with wire round the sides and ends, and stitched down the middle to further keep the straw in its place. With me these wire contrivances were of much more real use thus used in winter than ever I found them for supporting the Peas in summer; but if wanted for the latter purpose they can in this way be made to do double duty. A couple of these, or in some cases two and two, one above the other, secured to three stout poles driven well into the ground on the windy side of a shrub or young tree, the ability of which to stand in the position in which it is planted is uncertain, will often make all the difference between injury and escape from the keen frosty winds. The ordinary wattled hurdles used for folding sheep are equally useful employed in the same manner. It is not necessary that this protection should be wind-proof, but simply as a break to stop its coming in force against the plants.

I have heard two objections raised against the use of such means of protection; first, that they are unsightly in a garden, which must be admitted; but it is often simply a choice between tolerating such things in winter, or being without the plants altogether, unless content to put up with them in anything but an inviting state. The second objection is that it is useless resorting to means of this kind to shelter young trees that would soon outgrow any possibility of helping them in this way; but it frequently happens that trees—it is only those that are of an evergreen description that I am including in this kind of treatment—somewhat susceptible to injury from exceptionally severe winters are still more so for a time, from the fact of their growing luxuriantly, as they usually do in good ground for a few years after being planted, whereas after they have stood for awhile, and somewhat exhausted the soil within the immediate reach of their roots, they grow slower, and solidify their wood better, and are then better able to bear cold winds. Means, like those I have mentioned, that cost little in either labour or material, will frequently keep things safe, the loss of or injury to which would cause much disappointment; and after summers such as the one we have passed through, plants, as a rule, are in much worse condition for braving the keen winds of a severe winter.

T. BAINES.

The *Acer Ginnala* of the Amoor country, is a handsome hardy tree, which puts on the richest autumnal tints. In the sunlight the decaying leaves are of a singularly beautiful, glowing, ruby-red. The contrast between the autumnal tints of this species and those of the better-known North American *A. rubrum*, is very marked, the latter displaying but little deep colour, only a leaf or two here and there being partially or nearly entirely crimson, while the prevailing tint is a bright, clear golden-yellow.

A New Ornamental Willow (*Salix vitellina britzensis*) is recommended in the *Hamburger Garten Zeitung*, and, now that the

planting season is approaching, it may be useful to quote the recommendation. This novelty is said to have the bark of the young shoots coloured red, like those of *Cornus alba (sibirica)*, and, if so, the plant must afford a fine winter contrast to those of the golden Willow. It is in the hands of M. Späth, of Berlin.—*Florist*.

Scarcity of Berries and other Fruits and Seeds.—A very noticeable feature of the past untoward season is the remarkable scarcity of cones, berries, and other fruits or seeds on most of our hardy trees and shrubs, in almost every part of the country, except in a few isolated localities, chiefly in the north, where there appears to be an exceptionally full crop, especially of Mountain Ash, Hawthorn, and Holly berries. Throughout the southern counties, and as far north as York, a general scarcity prevails, and it is rare to see a tree well laden with fruits of any kind. The Oaks are destitute of Acorns, and the Spanish and Horse Chestnuts are equally barren. The Beech-mast is a poor crop, and generally nothing but husks; Hazel-nuts and Walnuts are more plentiful, but are mostly empty shells. Pines and Firs are generally barren of cones. Yews, Hollies, Thorns, Elder, Mountain Ash, Cotoneaster, Pyracantha, Snowberry, Wild Roses, and such like, are generally seen to be without a berry. With such an early fall of snow as has already visited the country, and the prospect of a severe winter following it, the general scarcity of these fruits will be severely felt by the "sweet songsters of the grove," whose principal store of winter food they usually supply. The general dearth will also considerably affect the supply of healthy and vigorous seeds of the various descriptions of forest trees, as well as of those trees and shrubs of a more ornamental nature; and except in cases of actual necessity, or where the seeds are plentiful and known to be thoroughly matured, it will be better not to save any seeds, for, if they do not prove utterly barren, they are only too likely to produce a weak and sickly progeny. From our correspondents in the north and east of Scotland, we hear that Holly and other berries are very abundant on trees where scarcely a berry of any kind was to be observed last autumn. Whether it was their barrenness last season, or an exceptionally favourable state of weather experienced there this year, that has been the cause of their fertility amidst the general barrenness of the present season, is a matter for careful investigation before any safe deductions can be made from such a remarkable exception. Most of the deciduous forest trees in these localities appear to have shared in the same fertile abundance of fruits or seeds, the Oak alone excepted, upon which there seems to be a universal scarcity of Acorns.—"Journal of Forestry." [In some parts, as in Kent, for instance, most of the smaller-growing Conifers, such as Thuja, Retinosporas, &c., are literally borne down by the weight of their cones.]

An Interesting Hybrid Conifer.—In his private garden at Verrières, M. Henry Vilmorin has, among other choice coniferous trees, an interesting and very handsome hybrid Conifer, obtained from a cross between *Picea Pinsapo* and *P. cephalonica*. We do not remember at the moment which was the seed-bearing parent, but whichever it may have been, a dozen cones were fertilised. Of these only one "set," and in this there was only one fully developed seed which gave birth to the plant in question. The specimen, which measures 8 ft. in height, and as much in diameter of branches near the ground, is thickly furnished, differs from both its parents in the arrangement of its leaves, and promises to make a distinct and noble looking tree.—"Journal of Forestry."

Wall Shrubs.—It is not generally known that the different varieties of variegated *Euonymus* make splendid wall shrubs; they require nailing at first, but ultimately they cling like Ivy, and will withstand the most severe winter in this position. I noticed some the other day planted between Clematises and other showy summer-flowering climbers. The *Euonymuses* (together with *Choisya ternata* and others) gave the wall a bright and cheerful appearance. I am convinced that the *Camellia* might be much more extensively used as a wall shrub than it now is; too often it is tried once, fails, and is not tried again. A lady recently told me that with her it was a much better shrub than the Laurel, and yet before she could get it to thrive she had tried it in every aspect, failing always until she tried it on a north wall, when it soon established itself, and has since given no trouble. While on the subject of covering walls, allow me to protest against the hideous cropping to which Ivy and other wall plants are subjected, and that even in the case of small villa gardens, thereby making them more Box-like, and the outline of their walls more visible and formal. It would be found to greatly improve the effect if a log, a few bricks, or stout sticks were placed here and there at irregular intervals along the tops of the walls to support the climbers, and thus break the straight line that is too often visible. A packet of seed of *Linaria Cymbalaria* (Toad Flax) sprinkled on old walls in spring would prove very satisfactory. The prettiest wall effect which I saw last summer was produced by this plant.—JAMES O'BRIEN.

The Ginkgo (*Salisburia adiantifolia*).—It appears that the males of Ginkgos attain a much larger size than the females; moreover, the males grow straight on and have wide-spread, ascending branches of free and vigorous growth, the female being closer, more compact, and the branches sometimes even pendent. In the garden adjoining the palace of the Grand Duke of Baden, at Karlsruhe, there are two fine specimens of Ginkgo. The exact measure of one is as follows: diameter just above ground, 29 in. : diameter at 3 ft. in height, 25 in. ; height of stem up to first branches, 19 ft. 4 in. ; total height, 84 ft. It is a very stately specimen. The Ginkgo was introduced in England about 1758.—MAX LEICHTLIN, *Baden-Baden*.

THE IRISH OR CONNEMARA HEATH.

(*MENZIESIA POLIFOLIA* VAR.)

THE flowers of the white varieties of this native plant may be classed amongst the most lovely of all delicate blossoms, and when seen

The Irish or Connemara Heath (*Menziesia polifolia* var.).

upon the plants, or when cut for use as domestic or personal ornaments they are able to compete successfully with even the most select of tropical flowers. During the past few years, blooms of the white varieties have been welcomed by Covent Garden florists, who make excellent use of them in the arrangement of bouquets; but it is as seen on the dark-leaved little bush as themselves that the spires of snowy bells are most attractive, and a rod or so of these plants 18 in. or 2 ft. apart would be a very serviceable addition to any garden where cut flowers of a choice character are desired, or a few plants might be used as a fringe to beds of Rhododendrons and other American plants. Although a peat soil is eminently suitable for these Heaths, nevertheless it is by no means an absolute necessity, as a good fibrous loam meets their requirements nearly as well, and, like most other plants, they evince a preference for pure fresh air. The type (No. 1 in the annexed illustration, the upper figure to the left), as found so abundantly in some parts of the west of Ireland, bears bells of a ruby-purple colour; (No. 2) *M. polifolia* var. *alba*, has snowy-white bells; then of this there is a large and more inflated form (No. 3) known as *alba major* or *globosa*, and the variety (No. 4)

named *M. polifolia bicolor* is perhaps the most singular of all in its changing variations, which range from pure white to deep purple, through all the intermediate tints of blush-white and pink, while some of the bells are distinctly striped with purple on a white or blush-coloured ground. All these variations may occasionally be found on the same flower-spike, as is shown in the engraving in the upper right-hand figure. Science has as yet taught us little or nothing as to the causes of colour mutations of the type here alluded to, where nature strikes a full chord of colour-music instead of the "harping on one string," which is more familiar to our eyes. In the type *M. polifolia*, and in the pure white forms, the decided colour ruby-purple, or the absence of colour pure white, are characteristics strong enough to bear down and overcome the others. Here, however, in the bicolor form the colours tremble in the balance; none of the tints are able to "kick the beam" either way. F. W. B.

AMERICAN NOTES

Cercidiphyllum japonicum or **Kadsura**.—I fully believe that this tree will not only prove perfectly hardy in Massachusetts, but will be valuable for shade and also as a source of timber. It is found sparingly in the mountain ranges of Nippon, and abundantly in the forests of Yengo, where its true home appears to be. So far as my observations have extended, it is but rarely found growing on bottom lands, or where there is a large accumulation of moisture, but it delights in the well-drained and gentle slopes of foot hills, along the base of which it forms a narrow belt, its zone of distribution, with reference to altitude, being slight, since it does not appear to thrive on the higher and more completely drained slopes. It is very common in the larger trees for the trunk to divide from two to five times, at a distance of 8 ft. or 10 ft. from the ground. Two trees of very common size were measured at a distance of 3 ft. from the ground, and in each case found to have a circumference of 27 ft. The common height appears to be between 80 ft. and 100 ft. The foliage is small, graceful, and compact, while the tree, as a whole, forms a stately and most beautiful object. The flowers are so inconspicuous as to be of no value for ornamental purposes, while the fruit, consisting of small pods about $\frac{3}{4}$ in. in length, would be no serious objection to the tree as an object of ornament, on account of its diminutive size, while any objection which might arise on this account could be overcome by taking care to select only the staminate trees for planting. Respecting its special value for timber, but little can be said as the result of experimental determination, and the question of durability can only be decided at some future time. The wood is light both in colour and weight, strong and easily worked. The grain is rather close. For fine indoor work and the manufacture of furniture, the Japanese employ it very extensively, while the Ainos consider it one of the best of woods for the construction of "dug-out" canoes, both on account of its lightness and strength, while they can also find an abundance of trees in which the trunk is perfectly straight and free from branches, for a distance of 20 ft. from the ground. It seems quite probable, from the uses made of the wood, that it must be of durable quality and that it will prove a valuable acquisition.

Orchids in the Open Air.—At the October meeting of the Germantown Horticultural Society, two species of *Stanhopea* were exhibited in bloom which had been hanging out in their baskets on the branch of a tree all summer. They were exhibited chiefly to show how easily this class of Orchids could be grown. One plant, *Stanhopea oculata*, had six flowers in its truss. Probably a large number of summer-blooming Orchids could be grown in this way.

Pine-apples.—The Banana has become so popular that the Pine-apple has fallen in proportion. They are not imported now to the extent they once were. The importation of Bananas is enormous.

Propagation of Peach Trees.—We were recently informed of an enterprising nurseryman, who bought at a high figure two plants of a new kind of Peach tree. He has 2000 first-class plants to sell this autumn.

The Phylloxera in California.—This pest is making such inroads among the Vineyards of California, where the European forms of Grapes have hitherto done so well, that the leading Vine-growers are thinking of following the example of France, and of grafting their plants on the native American stock, which has been found to suffer less from the attacks of the little root pest than others.

Picea and Abies.—As already noticed these have been confused. What we know is *Abies* should be *Picea*, and what are *Piceas* should be *Abies*. The Firs are the *Abies* and the Spruces *Picea*. About this Mr. Lemmon has the following in the *Pacific Rural*

Press:—"Dr. George Englemann, of St. Louis, the closest student of our trees in America, has just published an exhaustive description of the American Firs, in which he says:—"I follow Link in his name, definition, and limitation of the genus *Abies*, which seems to be a very natural one, comprising the Silver and Balsam Firs." The synonym *Picea* is the older name, and enjoys the Linnæan prestige, but is contrary to classical (see Pliny and others) and philological authority. The name *Abies* is generally adopted in Europe, while *Picea*, heretofore principally used in England, is now being abandoned. *Picea* is the Pitch tree, and properly designates the Spruces. Tournefort, the elder De Candolle, Gray, and others comprise under the name *Abies* both the Spruces and Firs; 'but,' Gray declares emphatically that 'the generic distinctions between them are abundant, and based on floral and fruit characters as well as upon the leaf anatomy.' The Spruces may be said to be distinguished from the Firs by their depending cones growing from any of the limbs, with persistent scales and bracts, and, generally, by their scattered limbs and leaves; also by microscopic anatomy, as shown by Englemann. They comprise two genera, *Picea* and *Tsuga* forming the second and third genera of the Abietine, differing from each other by but few characters detected at a distance; five species exist in California. Second genus, *Picea*, from *pix*, 'Pitch.' The true Spruce. Leaves four-sided, and generally scattered all round the long twigs, leaving, when they fall, the foot-stalk, persistent, ligneous, and prominent. Bracts concealed beneath the cone-scales."

The Bug Market.—It is said that the entomological cabinet of Mr. Andrew S. Fuller, contains 8000 species of beetles alone. Mr. Fuller estimates that there are over 100,000 species of insects in the United States. A gentleman who visited his collection says: "Here Mr. Fuller sat down at the table and began to write. The reporter was about to leave when the entomologist said 'I have given you the little I know concerning one beetle, but to-day there is not 100 of our North American insects whose true history is well known. There is room for 1000 active young men to distinguish themselves in this direction. The pursuit is most fascinating, and no man who has once entered it will ever wish to turn back. Just to give you an idea. One man visited Florida during the winter and brought back over 1500 new species of bugs. Another man broke down the bug market in one specialty. He found under a dead Palmetto fan hundreds of bugs that were previously rated at seventy-five dollars apiece.'"

Gathering Grapes.—The Californians have invented a ring to be worn on the forefinger of the right hand, to which a little short blade is attached, so that with but one hand the bunch can be at once cut from the Vine.—*Gardener's Monthly*.

The Bleeding Heart.—One of the finest plants for forcing in a house is the Bleeding Heart (*Dicentra spectabilis*). The roots of old plants may be taken up even now. Place them in a cool window or greenhouse, and they will bloom by the first of February, and continue to bloom until May.

New Potato.—A friend has shown us a specimen of a new seedling Potato which is said to be perfect as regards quality, and an abundant yielder. We may say that in appearance it is as shapely as the Snowflake which it somewhat resembles. It has been tested by Dr. Hexamer, who pronounces it the best Potato he has ever seen, which is very high praise. It has thus far been designated only as B.4. We suggest the name when this variety shall be offered for sale.—"Before."

Naming Fruits.—Mr. C. W. Garfield, secretary of the Michigan State Pomological Society, writes us the following concerning Kieffer's Hybrid Seedling Pear, and what he says we heartily endorse:—"Without having as yet fruited it, I have one objection to it, and that concerns its name. There is no use in trying to exhaust the description of a fruit by giving it a long time. 'Kieffer' is enough without having to run twice across a written page with the rest of the name. Our society will try and give short names to the fruits which it 'dubs.' For instance, two Strawberries we have named this year, the 'Marvin' and the 'Shirts' are models in brevity of nomenclature.

Curl in the Peach.—Professor Burrill, of Illinois, has recently made a thorough examination of the minute fungus which had long since been known to cause the curl in the leaf of the Peach, and states that the name appropriately given to this fungus is *Ascomyces deformans*. He has traced this fungus to the unopened buds. As the leaf expands it is carried along, and finally produces the well-known deformity. The young bark of a diseased twig is filled with the threads of the fungus, and is sometimes distorted with ridges and swellings and blister-like excrescences. Professor Burrill therefore recommends the pruning away in winter of such twigs as may be found to be thus diseased and committing them to the fire. To this we would add the importance of keeping the trees in a vigorous state of growth, as feeble ones recover less rapidly. The appearance of the curl is usually most conspicuous after a cold

period just after the leaves are expanded, this condition of the weather favouring the development of the fungus.

New York Central Park.—A blacksmith may be a very poor lawyer, and a shoemaker would probably show a want of skill in curing a sick man. In the same way a mere politician would not be expected to make a good landscape gardener. A writer in the *New York Times* points out the disaster which has befallen the Central Park since placed in the hands of party favourites. As examples of neglect, shrubs are untouched and straggle at will; trees are disfigured by trimming up; dead trees are left standing; young trees choked by weeds; rare trees dead from neglect; vistas closed by undue growth; structures decaying; large trees becoming lop-sided, and the whole a cause of sadness to those who remember its inception and early beauty.

New Agricultural Paper.—Mr. E. H. Libby, several years ago founded the *Scientific Farmer*, a monthly published in Boston. Several months ago he relinquished his interest in that journal to his partner, Dr. E. L. Sturtevant, to manage a new weekly which was to have been called *The Country Home*. It was advertised widely, but did not appear, because just at that time Mr. Libby preferred to accept the position of editor-in-chief of the *American Agriculturist*, and *The Country Home* was abandoned. For reasons not known to us, he soon retired from that position, and, after a brief visit to England, has now returned, and the first number of *Land and Home*, an agricultural weekly of which he is the manager, is now before us.

Menzies' Spruce.—Poor *Abies Menziesii*! We had grown to prize its steel-coloured leaves and peculiar looks in connection with *Menzies*. Dr. Englemann says we must drop it. If Colorado *Menziesii*, then we must call it *Picea pungens*; if Pacific *Menziesii*, then we must call it *Picea lichtensis*. The worst of it all is that *Abies* are *Piceas*, and *vice versa*. How scientists do keep things in an uproar!

Beurré d'Anjou Pear.—Marshall P. Wilder thinks the Beurré d'Anjou the best and most profitable very late Pear with which he is acquainted.

A Strawberry-coloured Apple.—We have noticed that several of our exchanges have of late made mention of a red Apple sent to them from somebody in Missouri. It is of medium size; skin straw-coloured, and the flesh is of a beautiful red Strawberry colour all through; rather dry, mealy, and with but little flavour; it is of but little value except as a curiosity. It corresponds in size, taste, and peculiar colour with the Surprise Apple, which is an old and well-known variety, and the probability is that they are identical.—*Rural New Yorker*.

The Pennock Apple.—A writer in the *New York Times* says that large quantities of this Apple (grown probably in New Jersey and Pennsylvania) are sent to the West Indies, where it is the most popular of all our Apples. Steamers frequently take 1000 barrels at a time during autumn. It is also largely quoted in the London market. The *Times* spells the name "Penich," and states correctly that it is a "characterless" Apple, and gives the proper synonym Pelican and the improper one Phoenix, the latter being a distinct sort, smaller, but somewhat resembling the Pennock.

Hardiness of the Pecan.—In answer to a recent inquiry as to the hardiness of the Pecan (*Carya oliviformis*) in Maryland, I can state that this tree is found in the forests of Illinois as far north as 42°, which is near the parallel of Chicago. It abounds on the borders of the Mississippi and Illinois river, and also in the Missouri Valley in the State of that name. The largest and best Nuts, however, come from Arkansas and Texas, and seedlings of these are found quite hardy here, where the mercury sometimes descends to 30° below zero. By selecting the best and largest Nuts for seed, great improvement is made in the size and quality of the Nuts. Bryant, in his "Forest Trees," says of the Pecan:—"No other Nut, native or imported, can be compared with this in flavour. The shell is thin, the kernel destitute of woody partitions, and easily extracted." The tree resembles the common Hickory, and, like that tree, should be transplanted at one year old from the seed. The trees are rather tardy coming into bearing, but are very productive after attaining sufficient age.

Early Freestone Peach.—Nearly all the very early varieties which have been brought before the public within a few years are alike in a strong adhesion of the melting flesh to the stone, and one in which the flesh separates freely from the stone has been sought. The *Canadian Horticulturist* describes a new sort, known as the Early Canada, in which the desirable characteristic is quite distinct. The fruit ripens about August 1, possibly a little after the Amsden, and it is described as of fair size (rather indefinite), bright in colour, of excellent quality, and nearly a perfect Freestone. It is certainly worthy of trial.—*Country Gentleman*.

ANSWERS TO CORRESPONDENTS.

Setting Boilers.—If "W. S." (p. 522) will set his saddle boiler low enough to permit of a gentle ascent from the outflow at the crown of the arch to the highest and most remote point of the flow and return pipes in the house to be heated it will work satisfactorily. A saddle boiler here which heats a plant stove and intermediate house 100 ft. long, is only about 4 ft. below the level of the top of the flow pipe nearly 100 ft. off, and about half that depth is taken up with the necessary elbows and branches near the boiler, otherwise the latter might have been at 1 ft. or 13 in. higher, or about 2½ ft. below the highest and farthest point of the flow pipe. The boiler thus set works admirably and gives no trouble, and several other boilers of different shapes are set about as near their work, and have been in use for many years. In the house in question the flow pipe has a rise of about 1 ft. or 15 in. in 100 ft.—J. S. W.

Anacharis Alsinastrum.—If "A. K." (p. 522) were a fellow of the Royal Botanic Society he would read in the report just issued the following:—"It is a remarkable fact that the American Water Weed (*Anacharis Alsinastrum*), which completely filled out not only the lake in the Society's Garden, but rivers, ponds, and other pieces of water throughout the county, and threatened to impede canal navigation, has lately become less troublesome. Since a pair of swans have been kept in our lake not the smallest patches of the weed have reappeared, and in other localities, where it was as great a pest as with us, it is no longer to be seen, and I have even found some difficulty in obtaining specimens."

Blue-flowered Greenhouse Plants.—"A. K." asks (p. 522) "What are the really best blue flowers for cultivation in a small warm greenhouse?" Has he tried *Ageratum*? We find them extremely useful, and the colour is unobtainable in any other plant during the winter months. Any variety of the Imperial Dwarf type is suitable for pot culture, but the favourite here is *Lady Jane*. To obtain a stock of this or of any other new variety, we sow in heat in the spring, and grow the young plants on for bedding out purposes. Some are planted in a mixed border, and the best of these—selecting those of good habit, and which are also likely to continue blooming for some time—are lifted with a good ball, and potted into 5-in. pots. If liberal treatment is given, they will flower freely during the winter, and in the spring will yield a quantity of good cuttings, from which we raise our stock for bedding out. We prefer this practice to raising them from seed, on account of seedlings generally varying in habit. We also treat *Lobelias* of this species in the same way as the *Ageratums*, and they seldom fail to give a good and continual supply of bloom, which brightens up the front row of plants in a warm greenhouse. Both *Ageratums* and *Lobelias* are in some places grown on in pots for winter work, and they well repay the trouble taken. If this plan is adopted, they ought not to be started too early in the season, nor be allowed to exhaust themselves by flowering during the summer. Both are gross feeders, and should be treated accordingly, *i.e.*, should be grown in good rich soil, and receive plenty of liquid manure.—W. T. O.

The best and most useful blue flowers that can be had at this season for the embellishment of a warm greenhouse are those of *Browallia elata* and *B. Roezlii*, both of which bloom profusely and afford choice sprays for bouquets, a use for which they are specially adapted, being small and of that character as to add a finish more telling and unique than could be attained by the employment of anything else, excepting, perhaps, a few sprigs of *Forget-me-not*, which are not to be had at this season. Here we grow them largely for cutting, and when kept in a cool stove it is surprising what a quantity of flower may be had from a few plants, as, after having their heads or main branches removed, they break again from quite the old stumps, the young shoots from which come crowded with blossoms. To have them good at this time of year, the seed should be sown in August, and the plants grown on in frames with plenty of air till the middle of October, when they require a warmer situation. We grow three together, placed triangularly, in 7-in. pots, in which way they make fine masses, and are more effective than they are when kept singly, as, being of spare, fragile habit, one alone looks thin and poor. Those who have not the good fortune to have some of these *Browallias* now, will find that by sowing at once in heat and growing the plants on in a temperature of 55° to 60°, they may have a fine display of them in April or May, a time when they will be most acceptable, and from whence they will last on for months in full beauty. The soil they delight in is a light, rich open one, such as about half loam and leaf mould, with a sprinkling of rotten manure, in which mixture they grow rapidly and maintain a healthy green colour.—S. D.

Slugs and Lapagerias.—If "T. C. A." (p. 522) will place a common lamp glass or funnel over the young shoots of his *Lapagerias* that spring from the root he will save them from slugs, which are fond of them. Woodlice should not be found in a soil and temperature suitable for the *Lapageria*, which prefers a moist and cool atmosphere.—J. S. W.

—*Lapageria* shoots burying themselves in is in a measure no doubt caused by the shoots meeting with some obstruction in their upward course, most probably arising from the hardness of the soil on the surface, and, the plants being unable to push through, naturally travel on further in their endeavour to find an opening. The tendency of *Lapagerias*, too, is to extend themselves by means of these underground shoots, which, even in a moderately loose border, often make their appearance far from the base, and put forth their heads where least expected. Long as I have had to do with *Lapagerias*, however, I have never known them to strike down towards the drainage, and I think if examined closely they will be found to be roots and not shoots that are making in that direction. The two are so much alike at first sight that it is an easy matter to be mistaken with regard to them, the first-named being very large and fleshy, resembling in that respect, those of *Asparagus*. If the wall surface which forms the boundary of the border is rough, as appears the case, the best remedy is to coat it over with a mixture of cement and mortar, which will set hard and smooth, and therefore when the points of the young shoots touch it they will meet with no obstruction, but work their way up the sides till they emerge and find light. Not only are slugs and woodlice very fond of the tender young shoots of the *Lapageria*, but worms eat their way into them likewise, and from the depth at which those mentioned by "T. C. A." are injured, it seems pretty certain that these pests are to blame for the mischief. Woodlice would nip them off at the surface, as would also slugs, to prevent the ravages of which it is a good plan to cover each young shoot when it makes its appearance with a lamp chimney till the young succulent end gets out of their reach. Meanwhile, the depredators should be trapped by the use of *Lettuce* leaves, or any other bait ready to hand. The best for woodlice is boiled *Potatoes*, placed in small flower-pots, with a wisp of loose hay on the top of it, so as to make a snug retreat while at their repast, and afford cover to hide.—S. D.

Schizostylis coccinea.—B.—No doubt your plants were weakened by being divided last year; but if not checked in their growth they will soon re-establish themselves and flower well next year.

Asparagus Beds.—Would ashes (burnt clay) do good put on *Asparagus* beds? and, if so, should they be applied now with the manure or in spring? Also, should salt be used now or in spring?—SUBSCRIBER. [Ashes from burnt clay or from any vegetable substance, or the two mixed, do good on *Asparagus* beds. Pass them through a sieve, and spread them on the beds just previous to the spring dressing, when they should be lightly forked in to mix them with the soil. They will open up the surface, let in the sun's warmth, and otherwise be beneficial. Salt is best used now with the manure; the dressing must not exceed 1 lb. to the square yard; in some cases less will suffice.—E. H.]

Cutting Down Dracenas.—Subscriber.—The operation had better be left until spring, when it may be successfully carried out.—G.

Epiphyllums.—Amateur.—The stock you mention we think will be unsuitable for the purpose. *Epiphyllums* are usually grafted on *Pereskia aculeata*.

Names of Plants.—H. F.—1, *Aspidium capense*; 2, *Asplenium lineatum bipinnatifidum*; 3, *Pteris longifolia*; 4, *Blechnum occidentale*.—J. E.—1, *Pasiflora corulea-racemosa*; 2, We cannot name number 2 without flowers.—M. T. W.—1, *Erica hyemalis*; 2, *E. mammosa*; 3, *Justicia speciosa*.—R. D.—1, *Salvia splendens*.—Enquirer.—1, *Nerine flexuosa*; 2, *Epidendrum ciliare*; 3, apparently *Oncidium aureum*; 4, *Brassia verrucosa*.—A. B. C.—A fine form of *Lapageria rosea*.—W. B.—The seeds sent are those of *Heraclium giganteum*.—T. E.—1, *Pellaea falcata*; 2, *Blechnum occidentale*; 3, *Aspidium acrostichoides*.—M.—We cannot recognise the climbing plant you send from such a scrap.—Dorset.—1, *Lasiandra macrantha*; 2, *Pteroma elegans*; 3, *Begonia odorata*; 4, *B. fuchsoides*; 5, *B. Rex*, var.—R. M. S.—Plants cannot be named accurately from leaves only.—Subscriber.—*Calceolaria glutinosa*.—J. L. O.—The *Calvary Clover* is no doubt *Medicago Echinus*.

Names of Fruits.—R. J.—1, *Golden Pippin*; 2, *Ribston Pippin*; 3, apparently *Northern Greening*; 4, *Cellini*.—S. M.—The *Pear* you send is *Doyenné du Comice*.

Books.—J. W. S.—Apply to Messrs. Reeve & Co., Henrietta Street, Covent Garden.—A. D.—The treatment of *Crotons* is given in vol. ii. of *Williams' "Choice Stove and Greenhouse Plants."*

Questions.

Oil Stoves and Glass Roofs.—I have had one of Lynch White's tubular boilers in constant use over fourteen years, and its work has been perfectly satisfactory; but the present severe weather makes one feel anxious in case a breakdown should happen. Would a few heating oil stoves be useful if an accident were to occur? I find some difficulty in keeping up the temperature in some houses I have had roofed without putty, the glass being bolted together and fastened to purlines with copper wire clips; it makes a difference of 5° or 10° as compared with roofs made with puttyed sashes. I should be glad to know whether this is usual.—AMATEUR.

THE LIBRARY.

We have received "*Alpine Plants, painted from Nature*," by Joseph Sebott, and edited by A. W. Bennett, F.L.S. (Swann, Sonnenschein, and Allen). This is one of those books devoted to Alpine flowers, which appear from time to time on the Continent, and which show the flowers in the skimpiest way possible, the poor little plants sticking up in the middle of the page as prim as pins, and often badly selected as to kinds. Of course we know *Arnica montana* is an Alpine plant, but at the same time it is like so many ragged weeds; and the *Centaurea montana* is another gem that might well have been left out; also the common Monkshood, and the still coarser yellow Monkshood, which grows about 8 ft. high when it gets a chance. It is all very well to say they are Alpine plants. Though they are mountain and sub-Alpine plants, we never saw such tall subjects associated with the very high vegetation in Alpine places. The printing is, however, clean and good, though hard in colour. As to the drawing, which is said to be by a distinguished man, it seems to be in no way different from the usual botanical drawings, which are of a very much lower order of merit than the horticultural public are generally aware of. The letterpress is of the usual pedantic description, beginning with "leaves lanceolate elliptic lanceolate," &c., and so on without mercy. V.

BOOKS RECEIVED.

Long Life and How to Reach It. By Joseph G. Richardson M.D. Philadelphia: Lindsay & Blakeston. 1879.
Hearing and How to Keep It. By Charles H. Burrett, M.D. Philadelphia: Lindsay & Blakeston. 1879.
Greenhouse Management for Amateurs. By W. J. May. The Bazaar Office, 170, Strand W.C.
The Hardy Fruit Book. By D. T. Fish. The Country Office, 170, Strand, W.C.
Life of Erasmus Darwin. By Ernst Krause. London: John Murray, Albemarle Street.
Illustrations of the British Flora. Drawings by W. H. Fitch, F.L.S., and W. G. Smith, F.L.S. London: L. Reeve & Co., 5, Henrietta Street, Covent Garden.
The Pear (illustrated). By D. T. Fish. The Bazaar Office, 170, Strand, W.C.

Show Potatoes.—Mr. Peter McKinlay's exhibition of these at the Agricultural Hall is worth going a long way to see. Amongst them are *Magnum Bonum*, *Woodstock* and *International Kidneys*, *Trinmph*, *Trophy*, and others, all picked tubers of unusual excellence. They were stated to have been manured with Amies' Potato Manure, of which Mr. McKinlay speaks in high terms.

THE CLIMATE OF THE RIVIERA.

A DEVONSHIRE correspondent says: "Your account of the climate of the South of France, which appeared in *THE GARDEN* (p. 499), is very different from that published in the *Exeter Gazette*. My own strong feeling is that on the whole—making a just balance of all the advantages and disadvantages, there is no place in the world superior to Devonshire, especially the South of Devon. The following is the account above alluded to:—

"From the Riviera.—It was on a Novemberish day, towards the end of October, that I paid a visit to a London physician, who had been putting me through a course of treatment which had not proved quite successful, and my spirits took their hue from the dull yellow haze that obscured the vistas of Hyde Park. 'Go to the Riviera,' said the good doctor, after we had exchanged mutual grumblings about the north-east wind and depressing atmosphere. 'There you will find a blue sky, a bluer sea, clear air, and glowing sunshine, and be able to be out of doors all the day long. Try San Remo first, for there you will sleep better, and afterwards go to Cannes or Nice, where the air is more exciting, and where there will be always something going on to interest and amuse.' This advice, though it came from a matter-of-fact German, was given with an Italian fervour that was irresistible. For three weeks I have been in the Riviera, and am now (1st December) at Bordighera. During the past fortnight I have experienced little else than wet weather, and have seen little of that glowing sun which was to invigorate and cheer me. For 36 hours up to this morning it has rained incessantly; and to-day, to vary the monotony, snow has fallen heavily, misty vapour veils the mountains from sight, and there are some 2-in. of snow on the ground, with much more to follow, if one may judge from the leaden colour of the sky and the keenness of the north-east wind that blows from the Alpine range. Unskilled in meteorological observations, I have been trying to glean information and hope from the weatherwise as to the prospects of the days to come. 'Mine host' declares that he has not seen such a downfall for ten years past, and seems to think that there is something dreadfully wrong in the weather arrangements somewhere, more particularly on account of news received from Milan that there have been greater snowstorms there than have been known for three centuries. The English doctor, who makes Bordighera his winter residence, looks seriously at the falling flakes, tells the company round him that the thermometer stands at the almost unprecedented point of one degree below freezing, and if it only goes 2° lower the Lemon crop will be imperilled, and dreadful damage done to vegetation generally. 'Why, it's a regular English winter!' say the English folk, who have come out like myself to see the earth bathed in sunlight, instead of covered with a mantle of snow; and they ask anxiously, 'When will it clear up?' The answer is not encouraging. It is to this effect: 'We usually have our rainy season in the Riviera in October, but this year it did not come at its appointed time, so that the Orange crop nearly failed from the drought. It has come now, and usually lasts three weeks.' To dissipate the blank looks which this announcement brings forth, the searchers after fine weather are further told that there will not be continuous snow or rain, but intervals of sunny days and laughing skies. As we have had a fortnight of changeable weather, hope is expressed that there is not much more to come. It was a wet season last winter, and two wet seasons in succession are considered to be scarcely probable. Visitors to the smaller towns of the Riviera are hard put to it at such a time as this how to pass the hours pleasantly, for when the sunny day interval arrives, the muddy roads and stony mountain paths are almost impracticable for pedestrians, so that the lovely walks with which the neighbourhood is said to abound can only be thought of, not undertaken. So to fill up an hour or two one feels inclined to inflict upon one's friends in Devonshire a few jottings anent one's journey to the Riviera and sojourn within its confines."

Severity of the Weather.—Accounts of this continue to reach us. Mr. James Backhouse, writing from West Bank, York, says: "On the night of the 6th inst., my four thermometers indicated respectively 4°, 4°, 6°, 6½°. The two former were partially influenced by the proximity of buildings; the others, in the open, were 200 yards apart, the last-named being 20 ft. below the preceding in position. This is the greatest cold here since Christmas Eve, 1860. The temperature continued below zero from about 9.30 p.m., on Saturday (when it registered 2°) till after sunrise yesterday morning. About 3 p.m. yesterday, (Dec. 8), a broad halo with prismatic colours encircled the sun."

— From Culford, Bury St. Edmunds, Mr. Grieve writes: "The maximum temperature has not exceeded 30° since the 1st inst. A considerable fall of snow occurred on the 5th; on the 6th the highest temperature was only 23°, and the lowest 1°, at an altitude of 4 ft., while a similar thermometer placed upon

the surface of the snow fell to 6° below zero. This is the lowest temperature experienced here since December 24, 1870.

— At Clumber the greatest amount of frost was experienced on the 7th, when the thermometer fell to 1 below zero. Many common Laurels are killed to the ground.

— Mr. Laxton says the lowest temperature registered at Bedford either this year or last was zero during the night of Saturday last, the 6th inst. Snow fell to the depth of 4 in. on the 5th. White Turnips seem injured, also Tea Roses where unprotected; autumn Cauliflowers and Broccoli are quite killed.

— At Bloxholm Hall, Sleaford, the thermometer fell on two occasions below zero, viz., on the 2nd 3° below zero, and on the 7th 6° below zero. A heavy fall of snow occurred on the 1st, also on the 5th, when 8½ in. fell. Laurustinus, Aucubas, common Laurels, and Portugal Laurels are killed to the ground.

— At Sandbeck Park, Rotherham, the thermometer on the 7th fell to zero.

— There were 25° of frost at Goodwood last Saturday night—the hardest frost that has been recorded there for a good many years.

Transmitting Plants.—The accompanying sketch represents the kind of box used by Messrs. Woolson & Co., of New Jersey, for transmitting bulbs of choice plants to this country. In such boxes we received the plants from that firm to which allusion is made in

Box for the transmission of Bull's.

THE GARDEN (p. 471). As previously stated, they arrived in excellent condition, the majority of them emitting young leaves as well as tender rootlets into the dry soil in which they were packed—sufficient proof that this mode of exporting small samples of bulbs is a capital one, and one that can be safely resorted to. The size of the boxes varied from 3 in. to 6 in. in length, with a proportionate diameter.

Messrs. Webb & Sons' Root Show.—Some magnificent Mangolds and Swedes were shown the other day by this firm; also some very fine Potatoes, including Webbs' Improved Schoolmaster and Webbs' Improved Magnum Bonum, the best apparently amongst some 500 kinds. Excellent Onions, Carrots, and other vegetables assisted in making the Wordsley stand complete. We noticed that no less than sixteen first and second prizes, in addition to several high commendations, were awarded to roots shown by this firm, a convincing proof of their superiority.

OBITUARY.

JOHN THOMAS WILLMER, for forty years proprietor of the Sunbury nursery, died on the 20th ult. at the advanced age of ninety-three. He was an enthusiastic florist, and did much in his time to promote the advancement of floriculture. He was the raiser of many new varieties in Dahlias, Tulips, Auriculas, Carnations, Picotees, and Pinks, for which during his career he won at various exhibitions nearly four hundred prizes in plate and money. He was also one of the founders of the Gardener's Royal Benevolent Institution.

"This is an art
Which does mend Nature : change it rather : but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES OF THE WEEK.

Lily of the Valley.—One of the prettiest sights that we have seen of late is a houseful of forced Lily of the Valley, in various stages of flowering, in Messrs. Veitch's nursery at Chelsea. Though the present date is somewhat early for their production, there was a fine batch in flowering condition two or three weeks ago. They are forced with great care; and a house is devoted to the purpose where abundance of moist heat, both at top and bottom, is available. Of course, later on, flowers may be produced with less heat, and the crowns also need not be so carefully selected for the purpose.

Dahlia Maximiliana.—This beautiful and rare species has been flowered and exhibited probably for the first time in Europe by Mr. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley. The plant is somewhat of the habit of *D. imperialis*, and like it growing from 8 ft. to 10 ft. in height before it flowers, but the leaflets are differently arranged. The flowers are also very dissimilar, as they more resemble in form those of *D. coccinea*, but the colour of the oblong ray florets is a pleasing deep mauve, and those of the centre a bright yellow.

Antignon guatemalensis.—We have received from Mr. F. Nevill Reid, of Ravello, Italy, flowers of this very beautiful Polygamous plant, which had been sent to him from India. It is a sub-shrubby climbing plant with slender branches and heart-shaped leaves. The flowers are about 1 in. across, and are of a bright rosy hue, disposed in numerous pendulous racemes. *A. leptopus* which is not unfrequently met with in gardens, is equally beautiful, but unfortunately it seldom flowers, and, consequently, it is almost worthless. The Guatemalan species is no doubt more floriferous, and would be well deserving of introduction.

The White-flowered Lælia anceps.—Some flowers of this lovely new Orchid will shortly be expanded in Mr. Bull's nursery, and no doubt Orchid lovers will be pleased to see it. Beautiful as is the typical kind, and also the exquisite Dawson's variety, this, in its purity and chasteness, quite surpasses them, and stands unrivalled as a pure white-flowered Orchid, though the white-flowered *Lycaste Skinneri*, mentioned last week, is a fit companion for it.

Salvia Pitcheri.—The dearth of blue flowers during winter is so general that any plant producing them at this season is doubly valuable, and the kind under notice, of which cut blooms bearing this name were brought by Mr. Cannell, of Swanley, to the meeting at South Kensington on Tuesday last, is one of the prettiest that could be used for winter decoration. The flowers are about the size and form of those of an ordinary bedding *Lobelia*, and are of a rich azurean hue, clustered upon a long stalk, forming a head from 2 in. to 4 in. long, which renders them very serviceable for bouquets, &c. Other species similar and nearly allied to this one are *S. azurea* and *S. angustifolia*, and, all being natives of Mexico or of the Southern States of North America, are therefore quite amenable to greenhouse culture, or indeed may be grown in the open borders during summer, and lifted and potted in autumn for winter flowering.

Fritillaria Karelini.—This pretty bulbous plant is now flowering in Mr. Ware's nursery at Tottenham. It grows from 4 in. to 5 in. high, with two or three stem-clasping broad leaves, and a terminal raceme of slightly-drooping bell-like flowers, which are about 1 in. across, pale purple, with darker veins and a few darker spots, with a distinct yellowish-green pit at the base of each reflexed segment. In general appearance it is quite unlike any of the ordinary kinds of *Fritillaria*, and it has been regarded by some as a species of *Rhinopetalum*. It is a native of Central Asia, and flowers in late autumn or early winter; therefore, it is a valuable and interesting plant for a winter-flowering collection of outdoor plants.

Candollea cuneiformis.—Of this uncommon New Holland shrub we have received some flowering sprays from Mr. W. E. Gumbleton's garden, Belgrove, near Queenstown. The bright canary-yellow flowers, about 1 in. across, and the deep green foliage, render it a very pretty and desirable greenhouse shrub, though, unfortunately, it is unsuitable for cutting on account of its almost stalkless flowers.

Luculia gratissima.—It is seldom that this charming Nepalese shrub is seen in flower in so small a state as may now be found in large quantities at Mr. Williams' nursery at Upper Hol-

loway. The plants range from 1 ft. to 18 in. high, and each stem is terminated by a large head of rosy, deliciously-scented blossoms, the appearance of which may not be inaptly compared with plants of *Hydrangea*. Such a sight as this at once suggests the question, Why is it not more valued as a winter decorative plant? Certainly it is not owing to its being difficult to manage, for in a warm greenhouse it is a very free-growing subject, and also very floriferous; it soon forms a handsome specimen. But perhaps the difficulty attending its propagation somewhat detracts from its being more generally grown.

The Ivory-flowered Angraecum (A. eburneum).—A remarkably fine specimen of this Orchid is now in flower in the Kew collection. The "break" is furnished with thirty leaves, and has six flower spikes upwards of 2 ft. long, each bearing a dozen or more flowers, the pure ivory white lips of which produce a fine effect, and render it a valuable decorative plant. There are also several beautiful species in flower just now, including a fine example of the rarely-to-be-met-with African *Ansellia*, bearing three large panicles of quaintly-spotted flowers.

Dombeya Burgessiae.—This is a very handsome Sterculiaceoous shrub or small tree, which may be seen in flower in the Palm House at Kew. It has handsome foliage similar to that of the well-known *Sparmannia africana*. The flowers are produced in clusters, and are cup-shaped, with a tassel-like tuft of stamens in the centre, including a few sterile strap-shaped ones. The colour is white, with a conspicuous central blotch of deep carmine with delicate radiating penicillings. It is a native of Natal and Zululand, and requires a stove or warm greenhouse temperature.

Senecio pulcher in the Greenhouse.—Mr. Burbidge lifted a plant of this which he did not like to see punished with the hard weather when it seemed to long to flower vigorously. Potted carefully, and placed in a warm house, it is flowering beautifully, and will continue to do so till after Christmas, proving, thus treated, a most valuable and novel flower for the greenhouse. The fact will, no doubt, be taken advantage of by those who provide flowers for that season. It would be very easy to grow a batch of plants so that they could be transferred to the house just in time to give a good bloom before and about Christmas.

The Champion Potato.—The *Daily Chronicle* reports that the Marquis of Lansdown, who is the owner of property near Kenmare, County Kerry, has sent 175 tons of the Champion Seed Potato to be distributed among his poorer tenantry for planting next crop.

The Winter Coral Berry (Rivina laevis).—This neat little stove shrub is at present bearing racemes of scarlet berries profusely; at all times of the year it produces its flowers and fruit, but more so in winter than at any other season. The individual berries are not more than half the size of those of the Red Currant, but their abundance makes up for deficiency in size, and, being most plentiful when scarlet berries are in greatest request, it would be an acquisition to those having to provide them. It may be increased rapidly by means of seeds, but the young plants require frequent stoppings when young, on account of their tendency to straggle. This and the other species are finely in berry in the Palm House at Kew.

The Weather at Vienna.—During the last three weeks the temperature has been about zero (Fahr.), and we have had frequent snowstorms. Yesterday (Dec. 8) the thermometer registered 9° below zero, and the cold, to all appearance, promises to continue. I am afraid that many of our choicer Conifers will suffer. Amongst others we have planted out Cedars of Lebanon, Wellingtonias, *Picea Pinsapo*, *P. Nordmanniana*, *Thuja gigantea*, and *Thujopsis dolabrata*, which have as yet sustained but slight damage. All kinds of outdoor work are now suspended, as the soil is frozen nearly a foot deep. This morning (Dec. 9) the thermometer indicated 13° below zero.—L. KROPATSCH, *Laxenburg.*

National Auricula, Picotee, and Carnation Societies.—At the annual meeting of these societies, which was held on Tuesday last, in the Council-room in the Royal Horticultural Society's Garden, at South Kensington, the dates of the exhibitions for the ensuing year were fixed; that of the Auricula Society is April 20, and that of the Carnation and Picotee Society July 27. The schedule, we understand, will be the same as that of last year, with the addition that prizes will be offered for seedlings in every class of both societies, and also for distinct species of the genus *Primula*. It was shown that the funds of these societies were in a flourishing condition, the balance in the hands of the treasurer being upwards of £33.

OUR readers will greatly oblige the Editor by sending any sketches of objects which would be interesting or instructive to engrave, particularly views of beautiful plants, trees, or good landscape gardening, or picturesque effects in planting or grouping.

THE INDOOR GARDEN.

FILMY FERNS.

THE account given in THE GARDEN, at page 579, of Mr. Cooper Forster's collection of these is most interesting. Many seem to imagine that they are difficult to grow. In reality no class of plants is more easily grown, provided always that the necessary moisture and shade are given. A sunk frame suits them admirably, protected with mats in frosty weather, although I believe many of the species will stand a touch of frost. In my filmy house there is no heat except what is borrowed from an adjoining stove. In this house there are about two dozen species of Hymenophyllum and Trichomanes. Among them are large plants of Trichomanes reniforme, very vigorous and showing signs of fruiting; *T. trichoides*, a large and vigorous plant on a block as imported; *H. demissum*, several plants, one very large; *T. alabamense*, new to cultivation; *T. Petersii*, *T. venosum*, &c. The walls are lined with Sphagnum, which serves to keep the house moist, and on it are hundreds of self-sown Todeas. The principal reason probably why this most interesting class is not more grown is the high price of plants at the few nurseries where they are to be had. Were the demand greater, perhaps the prices would be reduced, but until this is so it is worth while to import. Any one who has friends abroad, not necessarily botanical, might have living plants sent him at a trifling cost per post. I have received them in this way from New Zealand, and they are now growing vigorously. A slice of the bark or other substance on which the Ferns are growing should always be taken that the roots may not be disturbed. Put up in a small box with a little damp Moss, and enclosed in oil skin on india-rubber sheeting, they will keep fresh a considerable time. India-rubber sheeting only weighs $\frac{1}{2}$ oz. per square foot, and can be had from any druggist. Were prizes offered at some of the principal flower shows for Trichomanes and Hymenophyllums, probably it would have the effect of inducing their cultivation more generally. What more beautiful objects could there be for cases or bell-glasses in dwelling houses, instead of the miserable sickly Adiantums and other similar Ferns struggling for existence that one so often sees? Filmy Ferns would give infinitely less trouble, and instead of being a worry, as is too often the case, would prove a source of continual pleasure. Gas gets the blame of spoiling Ferns in rooms, but with closed cases of Filmy Ferns it has no bad effect.

Rockville, Murrayfield, Edinburgh.

P. NEILL FRASER.

ADIANTUM FARLEYENSE.

Few plants have attained a more deserved or wider popularity than this beautiful variety of Maiden-hair Fern. Like most other plants it had to pass through the trying ordeal that most new or rare plants do, viz., being overdone with kindness when first introduced by being grown generally in too high a temperature and in too light a soil, which, by the way, is a common error in the case of many other Ferns; for I have no hesitation in saying that since we have substituted a compost of nearly all turfy loam and sand for one formed principally of peat, and reduced our night temperature to that of a warm greenhouse, or to a minimum of 55° in winter, and 65° in summer, we have much finer plants in one year than we used to get in two seasons' growth. At present we have some fair sized specimens of it in 8 in. and 10 in. pots that were only taken off in the form of single crowns with one leaf attached to them last spring, for, when robustly-grown they form such large fronds that it does not take many to form a large plant. When fully grown they need support, as the weight of the leaf is too great for the leaf-stalk, and for this reason large plants of *A. Farleyense* will never be so generally useful as the smaller-leaved section of the Adiantums; but as specimen plants for exhibition, or for indoor decoration, when large single vase plants are required, there are very few plants that can surpass well-grown specimens of this noble Fern. It is readily increased by division, and being a free and continuous grower, large specimens of it may be secured in a limited time. It delights in abundance of moisture at the root, good drainage, and a moderately moist but not over-exciting atmosphere. Its highest beauty is attained when a large crown of young fronds is thrown well above the older ones, just as they have assumed that rich sunny tint so peculiar to the transition state, to the deep green of the fully-matured leaves. *A. Farleyense* is well worthy of a foremost place wherever Ferns are grown or leaf beauty appreciated, as it is always an agreeable subject for mixing with flowering plants, and at this comparatively dull season of the year a few plants of it do good service if mingled freely with Calanthes and other beautiful flowering plants that are greatly benefited by the addition of the highly-ornamental foliage of this and other plants of a similar character.

Linton.

J. GROOM.

TRAINING CHRYSANTHEMUMS.

Now, when the Chrysanthemum shows are over for this season, it may not be out of place to enquire if some modification of the existing style of training would not be of benefit both to the growers and to the plants; for I never yet met with a grower who followed the stiff and unnatural mode of training now generally practised from any idea that he was improving the appearance of his plants, but simply because if he competed for the prizes offered at Chrysanthemum exhibitions he must make his plants submit to a system of training which was for the time being the fashion. Under such conditions the Chrysanthemum shows but a fractional part of its beauty. I have lately seen a good many Chrysanthemums trained in the form of standards with clear stems a yard high, and on the top of the hedge stake that supported the stem, which from its style of training was unable to stand alone, was an inverted cup-shaped wire trellis, on which the shoots were as tightly tied down as a prisoner to a rack. For the amount of labour that is expended on these monstrosities the arbitrary rules of societies are chiefly to blame. The training in question effectually destroys all claim which the Chrysanthemum has to rank as a decorative plant, and as to supplying cut flowers no one would expect to cut them so good from a trained as from an untrained plant; for the pinching, stopping, tying, and twisting to which the shoots are subjected all militate against the production of perfect flowers. A Chrysanthemum bush growing in the open air with just support enough to guard it against wind-breakage, is really when in flower a striking object; and when grown in pots under the protection of a glass roof, it does much to enliven our conservatories and cool houses in autumn and early winter, and the less staking and tying it gets the better. What some straggling growing kinds require to keep them erect should be given them early in the season, so that they may outgrow all signs of formal training before they are in flower, and nearly all the small flowered sorts look best without any training at all. But to tie foliage, flowers, and all down to a flat uniform level, and to expect a satisfactory result, is an impossibility. Chrysanthemum societies should obliterate all rules as to how the plants are to be fashioned, and merely offer prizes for the most effective plants or groups of plants.

Linton.

J. GROOM.

Standard Plants.—The objections to these raised by "J. G. L." (p. 505) seem to me to be altogether fallacious. The very object and purpose of these standard Ivy-leaf, Cape, and other Pelargoniums, Fuchsias, &c., is to obviate the flatness incidental to plants of even height in houses. If standards are intermixed with these the very best effect is produced. The objection to bare stems is removed if the plants are intermixed with others; but it should be specially pointed out that one object in recommending the growth of certain plants as standards is to enable them to display their natural drooping or pendent habit of growth to advantage; and when this is done the bare stems are hidden. What can be more unnatural than to see the charming Ivy-leaf Pelargoniums exhibited as pot specimen plants tied up in pyramidal form? The charm incidental to the drooping habit is lost, and natural growth is inverted. Worked on 2-ft. stems, as advised, their shoots would hang down in elegant profusion, and all tying might be dispensed with. What plant makes a more graceful standard than the Fuchsia? and when its robust, pendent growth, full of bloom, is permitted to hang down naturally all round the stem, the latter does not present an objectionable feature. The bare stem might be regarded by "J. G. L." as undesirable in the Princess of Wales Capsicum, or in some forms of the berried Solanums; but surely such an objection would be exceedingly limited. Most persons are only too pleased to get small standard berried plants to be concerned about the stems; and the same remark applies equally to larger standard plants.—A. D.

External Coverings for Heated Houses.—During the late severe frosts we have tried external coverings when much fire heat would have been injurious to the plants inside, and it is surprising what a difference even a thin covering like that of tiffany, or ordinary shading material, makes in keeping the cold from acting on the glass, and thereby robbing the internal atmosphere of its heat. I feel confident that it would be good economy to have hothouses provided with strong thick roller blinds if such winters as the last and present were the rule instead of the exception, as the saving in the way of fuel would soon repay the extra expense of coverings, to say nothing of the advantage to the plants by avoiding the excessive heat forced into the house to counteract the outside cold. In fact, both on the ground of economy and efficiency, good permanent roller blinds should be considered as indispensable to forcing houses as the heating apparatus itself. They would obviate sudden changes of temperature, and would be equally useful both in winter and summer, for although in our variable climate extremely high or low temperatures are comparatively rare, they are

all the more trying when they do come, from the unprepared manner in which they find us. If it was an annual occurrence for the thermometer to fall to zero, I have no doubt that we should quickly adopt external coverings to heated glass houses; for, as before stated, the very thinnest material has a marked effect in counteracting severe frost, and with a good woollen protector over the glass the work of the boiler would be greatly reduced.—JAMES GROOM.

DECORATIVE SPECIES OF ASPARAGUS.

WERE the common *Asparagus* (*A. officinalis*), a plant of recent introduction, it would be eagerly sought after on account of the singular beauty of its feathery foliage, or even had it not proved to be an excellent vegetable it would have been a common occupant of our flower borders. Its foliage is attractive in all stages, whether it be the soft delicate green when its hair-like leaves first expand, the rich green of summer, or the golden tints which it assumes in autumn studded with bright orange berries. This type of foliage is peculiar to the genus, no approach to it is to be met with in any other class of plants nearer than the deeply cut foliage of the Fennels or the Horsetails (*Equisetums*). It is usual to speak of these hair-like divisions as leaves, but though they serve the purpose of true leaves, they are only flattened branchlets, termed cladodes. The true leaves consist of greyish or brown triangular scales at the point of origin of the branches, and tufts of cladodes, which are sometimes transformed into spines. These cladodes or false leaves vary in size from $\frac{1}{4}$ -in. to 2 in. or 3 in. in length, and from the thickness of a hair to $\frac{1}{2}$ an inch in breadth, and they occur on the shoots either singly or in whorls or tufts (fascicles), similar to the arrangement of the needles of Pines and Firs.

A few of the species of *Asparagus* are quite hardy, but the larger part of them require to be grown under glass, being natives of the extra-tropical parts of the Old World. The flora of South Africa is especially rich in these plants, and the majority of our ornamental kinds are from that region. The hardy sorts and a limited number of the tender ones, are deciduous, with erect, self-supporting stems; but by far the greater portion have slender climbing perennial stems with spreading branches, some of which make elegant conservatory climbers. Their culture is of the simplest kind; their requirements being a light rich soil with plenty of root accommodation, an abundance of light and air, and a temperature of from 50° to 60°, and they are increased by division or by seeds.

There are two distinct modes of cladode, or false-leaf arrangement, among the climbing species; one in which they are compressed so as to form with the twigs flat branches, as in the Yew; and the other where they are arranged in tufts or whorls on erect or drooping branches, after the manner of the needles of the Cedar. Of the first group the most noteworthy are:

A. consanguineus.—A slender, scandent plant, growing to the height of 8 ft. to 10 ft., with numerous lateral shoots from 1 ft. to

2 ft. in length, which have a tendency to ascend and recurve. Its cladodes, which are hair-like and curved, are in fascicles of eight to ten each, and its flowers, which are greenish-white and pendulous, are followed by bright orange berries. It is one of the best slender cool-house climbers, suitable for training up pillars or rafters, and its foliage is serviceable for cutting.

A. Cooperi.—A more robust plant than the preceding, with a stiff spine at each joint, and numerous spreading flat branches. Its slightly curved cladodes, which do not exceed half an inch in length, number from six to fifteen in a fascicle. The flowers are not very showy, being rather greenish, with yellow anthers, and they are produced in clusters of from two to five at the base of the fascicles; but the foliage alone is sufficient to recommend it.

A. plumosus is of a similar habit to both the foregoing, but a far more elegant plant than either; indeed, for the exquisite fineness of its foliage it has no rival among flowering plants, and in grace it quite equals some of the fine-cut hair-ferns, such as *Trichomanes Pluma* and *fœniculaceum*. Unlike our garden *Asparagus*, its stems have a flat frond-like appearance, and the whole plant in a young state is not unlike *Asplenium ferulaceum*, but much finer as regards cutting. As it becomes older its stems become scandent, but its lateral branches retain all the elegance of the juvenile state. There is probably no more useful plant known for associating with cut flowers, as it retains its freshness for several days. It is a native of Natal.

A. scandens.—In dimensions this comes near *A. Cooperi*, but the cladodes are totally different both in size and arrangement; they are quite four times the width and twice the length, and in tufts of three or five. A spray is not unlike a fragment of *Taxodium*, but with polished green twigs. The flowers, which are pure white and droop from the tufts of false leaves, are succeeded by scarlet berries. This should be much more grown than it is where cut foliage is required, as it retains its freshness for a very long period, a remark, it may be observed,

A spray of *Asparagus consanguineus* (one half natural size).

which applies with nearly equal force to them all.

A few of the best of the whorled types are:

A. æthiopicus, a species with a slender climbing stem and spiny joints and cladodes, from 1 in. to 2 in. in length, in clusters of six or seven in each, and axillary racemes of pure white flowers with red anthers. The three-leaved variety of this is a much finer plant than the type, and one which seems to be specifically distinct. It blooms from August to October, and is a native of Tropical and South Africa.

A. ramosissimus.—A slender climbing species with drooping branches and flat shining acute cladodes in fascicles of five or six, and numerous white pendulous flowers. A common South African plant.

A. falcatus has the largest cladodes of any of those enumerated, being 2 in. or more in length, and arranged singly or in twos or threes. It has slender green polished stems and flexuous branches, with foliage of a dark glossy green.

A. virgatus.—A plant which comes near the common Asparagus in habit, not being at all scandent; has a perennial wiry stem supporting a conical plume of foliage. A very suitable plant for pot culture and conservatory decoration.

A. crispus.—This is the same as the plant known by the names of *A. decumbens* and *A. plumosus*. Its numerous stems are too slender to bear the weight of its foliage without support, consequently it assumes a pendent habit. Its cladodes are about $\frac{1}{2}$ in. in length, slightly falcate, and arranged both singly and in fascicles. Its flowers are solitary and inconspicuous. It makes an elegant basket plant, and a more effective curtain plant than many used for this purpose. Also a native of South Africa.

Of the hardy kinds *A. verticillatus* is a fine ornamental plant with greyish-green stems, varying from 3 ft. to 5 ft. in height, and lateral shoots decked with innumerable whorls of delicate green cladodes. This would have a beautiful effect if planted by the margin of a watercourse, with a groundwork of Butter Bur (*Petasites*) or Marsh Marigold. A native of South and Eastern Europe.

C. M.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Treatment of Phalænopsis.—In passing through a garden the other day that is managed by a friend of mine, I was struck with the satisfactory result of a suggestion which I made some eighteen months ago with regard to the treatment of a collection of *Phalænopsis*, which is a speciality in the establishment in question. At the time I mention the plants, some 150 in number, were in a deplorable condition, with scarcely a leaf on them, and covered with spot, the few spikes which they had thrown up being weak and poor. They were suspended in baskets in a span-roofed house, with a Peach house at either end, partitioned off with the ordinary glass divisions. Under the stage was a shallow tank filled with water, the service pipe for the houses being run through it, and creating a continual steam. The house was kept densely shaded, and very close and warm. I was asked if I could assign any reason for the unsatisfactory state of the plants—a question which led me to explain the conditions under which I had found them growing and collected them in the Philippines—conditions widely different from the artificial treatment to which they are generally subjected at home. I suggested more light and air, and in order to ensure a continual current in the house, I recommended knocking out some panes of glass in the partitions at either end; my suggestions were carried out, and the result was that many of the plants that then were barely existing have made four and five leaves of good size and substance, and of that dark glossy hue which indicates robust health; and they are throwing up spikes that promise well for a fine display of bloom. My friend tells me that when he has air on the Peach houses the baskets swing about. The owner is so far satisfied with the result of the experiment that he has since tripled his previous collections.—W. CHAPMAN.

Anthocercis viscosa.—This is a free growing evergreen greenhouse shrub, which all through the spring, summer, and autumn months produces its large salver-shaped flowers amongst its blunt or obovate foliage. The fine partite limb of the flower is of snowy whiteness, the broad tube being striped with green inside, and the flowers, although not particularly showy in character, owing to their large size, distinct form, and the length of time during which they continue in perfection, render this plant a desirable one for all botanical and perchance many general collections. The blossoms are produced from the axils of the leaves, which are regularly arranged alternately, and the flowering branches are from 1 ft. to $1\frac{1}{2}$ ft. in length. It is a native of New Holland. Our sketch, (p. 539) made from a specimen in the Trinity College Botanical Gardens, Dublin, shows the natural size and contour of the flower and leaves.—F. W. B.

The Roman Hyacinth is already in full bloom, and is doubly welcome amid the frost and snow. It seems a pity that the so-called blue Roman Hyacinth is so far inferior to the white. The latter is really invaluable for vases and bouquet purposes, and also as a pot plant from November till January.—D. T. FISHER.

Early Violets.—Mr. Groom (p. 459) speaks highly of the Neapolitan for early blooming. I have grown it for several years and have now a large frame half filled with it, the other half being planted with the more recently introduced Marie Louise, which has proved itself to be by far the best of the two. This variety has been producing abundance of very large blooms since the end of September, and promises to continue doing so for months to come, whilst the Neapolitan, under exactly the same treatment, has not as yet produced a bloom; it probably will bear blooms by-and-bye, and whenever they do come they are sure to be appreciated, but for the future I have made up my mind to depend chiefly on Marie

Louise, which I find to be a more robust grower, much earlier, and the blooms larger and also sweeter scented than those of the Neapolitan. Any one propagating and growing this variety as Mr. Groom recommends the Neapolitan to be grown, will, I am sure, find it to give satisfaction and also to be one of the finest varieties in cultivation.—H. HARRIS.

Orchid Culture.—The communication of Mr. Thomson (p. 435) to the effect that Dr. Paterson grows his Vandas and East Indian Orchids very successfully in a temperature where people can "sit with perfect comfort by the hour at all seasons of the year" will interest Orchid growers. Hitherto these plants have been grown well in warm houses, as the fine specimens in many public and private gardens testify, but if they can be grown in a greenhouse it will place many fine subjects within the reach of cultivators who have not hitherto attempted their culture. It would be well to have further information, however, and I dare say many growers besides myself would be glad to have a correct account of the temperature maintained in Dr. Paterson's houses if Mr. Thomson or the Doctor would furnish it.—CULTIVATOR.

Autumn Crocuses Protected.—Mr. Burbidge informs us that he has preserved and greatly added to the beauty of his tufts of *Crocus speciosus* by covering them with a large bell-glass. The "cloches" would be admirable for this purpose, as the plants could be seen so well within. It is probable that a number of plants, such as the Double Meadow Saffron, and the new autumn flowering Crocuses now being introduced, would be a great deal better for similar treatment—at least in many districts, and on certain soils.

LEAFLETS.

MR. PETER VEITCH has sent me some photographs taken in the beautiful Botanic Garden at Sydney, New South Wales, which is now so well managed by Charles Moore, formerly of the Botanic Gardens, Regent's Park, and brother to the late David Moore, of Glasnevin. It would be delightful to us northerners who know him to see him at home amidst all those beautiful plants. The scene is very different to the old herbaceous ground in the Botanic Gardens, Regent's Park. Exquisite plumage of Palm, fine-foliaged plants, delicate tracery of Acacia, great leaves of Agave, and strange Aralias adorn these "mixed borders," and form a combination such as we never see at home. And then there are Tree Ferns in all stages shading the garden, fountain, and stream, and very beautiful they are, as one would expect, in the collection of one who has had so much to do with collecting Tree Ferns.

It is difficult to realise the beauty and the character of Tree Ferns in our houses; they want to be standing free in the open air, in which position also the singularly marked bark often shows to good effect. It is still more difficult to realize the beauty of Palms and the Cycads in our cramped houses; in such a garden as this one really sees their beauty for the first time; a Palm—I never had the least idea of it till I saw it in the open air, its wonderful lines thrown against the sky. Among all this Sydney vegetation, what appears to be a Weeping Willow is in its glory, and, contrasted with Tree Fern, Palm, and Arum, and Papyrus, affords the most bewitching effect in the garden. I do not, however, see the Bamboo playing so graceful a part as it often does in the gardens of southern Europe.

Mr. John Murray, in referring to my "leaflets" on Goodwood, tells me that similar fine effects from the planting of Cedars on a large scale are seen at Highclere, a place I have not had the pleasure of seeing. But how much there is to be done generally in creating new landscapes, so to say, by the bold use of the Cedar of Lebanon and other noble hardy exotic trees! For such a home landscape as that at Goodwood is essentially distinct from what is generally seen in country seats.

Mr. Jean Sisley writes me from Lyons that they have had 3° below zero Fahrenheit of frost, which is quite exceptional in that country and at this time of the year. It has not before occurred in this century. They are afraid that a great many plants will be killed, particularly the Tea Roses; the Fig trees will probably be injured, and the Vines also.

I hear that Mr. Burbidge is making a very complete collection of Narcissi at the College Botanic Gardens; and a very good plan too. Of all the flowers of the northern world these are the only ones which really brave the vicissitudes of our spring, and such an attention will be well repaid, especially on a soil where they grow so well. It is an excellent plan for amateurs and others to take up one family and do it well; and they can scarcely do so without adding to our knowledge, and probably to the garden treasures of the country.

It is proposed to remove the hothouses of the city of Paris from La Meutte, their present place, to Le Parc des Princes, in the Bois de Boulogne. Paris is very well supplied indeed with public nurseries, both for hardy and tender plants, and the glass department is so arranged as to be a useful establishment, open to the public in a reasonable way, apart altogether from its use as a nursery. Some years ago it was an exceedingly interesting garden, and many fine plants were introduced there, and valuable experiments made. In the future, and in a more open locality, it will no doubt be no less interesting and useful.

Mr. Frank Miles tells me that he has got many of Regel's new plants in his garden, which he hopes to flower during the coming year. It is delightful to get new and beautiful or strange plants from these great wild regions of the northern world. No doubt they yet contain many lovely plants which we should be glad to see alive in our gardens.

It is most pleasant to read the American rural journals, and see the evidence of the rapidly-growing taste for the more beautiful side of gardening, so to say, and the intelligence and ability with which it is discussed in them. With such a fine and varied climate, the abundant and beautiful native flora, and capabilities of growing the plants of other countries to a vast extent, the future of ornamental gardening in America is big with promise. The name of the good old house of Parsons, of Long Island, is very frequently seen in the best work of this kind. *Scribner's*, a magazine of general literature, has lately taken up topics of gardening in a most spirited way, and illustrates the articles beautifully, the matter also being very good.

I also like the spirited way in which good Americans help their country and their youth, rather than seek to "found a family" and taking care that they have the least possible amount of motive for exertion. By the will of John Hopkins, it is stated in *Scribner's Monthly*, a merchant of Baltimore, the sum of 7,000,000 dols. was devoted to the endowment of a university and a hospital, 3,500,000 dols. being appropriated to each. This is the largest single endowment ever made to an institution of learning in that country. To the bequest no burdensome conditions were attached. Among the few definite provisions of the will was one requiring that all building and other expenses should be defrayed out of the income, leaving the capital untouched. Clifton, the estate of the donor, and forming part of the bequest, contains over 300 acres, and is situated three miles from Baltimore.

Mr. Horne, Curator of the Botanic Garden, Mauritius, is in England, and gives me a glowing account of the charms of the

Sydney gardens, and also of the vegetation of the gardens in some of the South Sea Islands. I was surprised to hear of the loving care with which some of the natives cultivate the many plants in their gardens.

I looked into the academy to see the students' work, and was much pleased with a very spirited landscape, by Mr. Frank Miles, for which he received an extra medal. Mr. Miles, as many readers of *THE GARDEN* know, is an enthusiastic grower of hardy plants, and in its columns I have often been pleased to read his notes thereon.

In this age of beer, tobacco, and champagne, it would, perhaps, be a good thing if more of our young artists had like tastes. They have a good deal to do yet, among other things to paint an English garden. I never knew anybody come so near it as Fred Walker. If anybody should leave me a fortune, I think I would found a prize for the best picture of an English garden, without crockery-ware, geometry, water-squirts, or much brick or stone.

I went to a little exhibition at an artists' club some time ago, and found the smoking creatures there in a fog of Tobacco such as would kill any ordinary insects. The pictures on the wall, however, were not such as made one regret beating a hasty retreat. Next day in walking through one of the Greek rooms of the British Museum I was led to wonder if any one of these men could ever produce anything worthy of mention in the same breath with what is so full of human dignity and grace that one is lifted by the mere sight of it clean out of this world of mud, smoke, and gin palaces.

However, about art in relation to gardens, the most deplorable thing at present is the state of botanical drawing. The stiff, hard, and poor flowers that are drawn, and the nightmare horrors by botanical artists that are announced with a flourish are too much for human patience; and yet, in spite of all the laughter and sorrow they excite, they continue to appear. The worst of the botanical artist is that he thinks he is quite safe when he only takes due notice of one fact or set of facts. He counts the petals and probably measures the diameter, and gives one a hard and unnatural effect.

Some people make an inexact criticism of such work by saying that it is faithful, but it is "not artistic." The criticism is just as wrong as the drawing. The play of light and shade, the delicate gradation of the parts, which are so exquisite in many plants, have just as much, if not greater value, than the fact they condescend to take notice of. Sometimes I have noticed botanical drawings in which, while the petals are counted exactly, no notice is taken of undulations or charm of petal that could not be counted, and was, in fact, ignored. I asked an artist, with no pretensions to be botanical, to draw a plant that had been thus treated, and here I was amused to find that he had taken notice of the delicate waving of the petals, while he was also as right in his count as the so-called botanical artist.

At Goodwood this year the Peach tree were destroyed by a very cold easterly rain which fell on them in June. Mr. Rutland, however, does not despair in the least of soon having good crops again, and has already planted some vigorous young trees. He believes, as I do, that a coping is necessary, not merely a wide temporary one to save them from the frost, but also a narrower and permanent one of tiles, brick, or stone, which would, at all times, protect the wall from a very cold or

sleety rain. The Peach is a tender tree, and where success is desired, must not be exposed on a naked wall without a coping, a state of things which may be seen every day, even in well managed gardens.

There has been so many failures of the Peach tree in the open air, even in the south of England, of late years, that I read with pleasure the following in the *Journal of Horticulture* :—

Although I have to contend with the cold climate of Roxburghshire, as far north as the Tweed, yet I have had good crops of Peaches on walls during the last ten seasons, and the trees now promise well for future bearing. My wall is 14 ft. high, 130 ft. of the southern aspect being covered with Peach trees, the other portion being devoted to Apricots; and although I lost many valuable shrubs and ornamental trees last winter, only a few small dead branches here and there on the Peach trees indicated the severe frost to which they were exposed. The Royal George and Noblesse are the two varieties which succeed best with me.

The fact is, where the trees are exposed vertically on the walls it is simply ruinous to them. In addition to a wide temporary coping (which should be removed when all danger of frost is over) there ought to be a permanent coping of 6 in. or 8 in., which would save the trees at all times to a great extent from the effect of cold vertical rains. This coping ought to be deep in proportion to the exposure of the wall to prevailing winds and storms.

Mr. W. Taylor, in writing a very sensible protest against hard pruning in the same journal, says :—

"In a very few years I expect Quince and Paradise stocks to follow the road which I am now happy to see standard Brier stocks are taking, and we shall have discovered afresh the astounding fact that a very good Pear can actually be grown on a Pear tree—a fact tolerably well known to our great grandmothers, but one which we modern scientific horticulturists have either lost sight of or willfully ignore."

As regards the Quince and the Paradise stocks, this is going some distance along a wrong track. What we ought to hope to see is a keener appreciation and fuller knowledge of the great advantages which the different stocks afford when used by the intelligent grower. What we already know of stocks seems to promise that much more has to be learnt, but what is already done by skilful cultivators for the market is most valuable. In all the great fruit-growing districts, both in this country, on the Continent, and in America, there is no lack whatever of trees on their own stocks, so to say, but the best men know also that kinds and conditions every day occur which require the aid of either the Quince or the Paradise stocks, and some other kind of form than the standard. There are even varieties which do not thrive as standard trees, but when treated otherwise are excellent.

For example, in the same number there is a note from Mr. Luckhurst, which shows how other forms besides the standard may prove useful or essential :—

"The value of walls for delicate Pears has been well shown this year. Excellent fruit of Doyenné du Comice are just now ripe from a tree on a west wall—a month later than usual; but the fruit on a couple of fine pyramids was not half grown, and quite worthless. It was the same with certain other varieties, and it is also noteworthy that wall trees both on east and west aspects had full crops of useful fruit, in pleasant contrast to the barren condition of most of the pyramids."

Nevertheless, there can be no doubt that in gardens not nearly enough attention is paid to standard trees; and it is rare to find an orchard in a country seat. Much more rare is it to find one fairly well-managed.

Mr. C. W. Dod makes a few much needed remarks on plant names in a contemporary.

"Will not some one who has influence in high places intercede to save gardeners from the dreadfully long names which are now adopted

for new flowers? Daffodils are the worst offenders. New varietals are coming fast upon us with such names as *Narcissus incomparabilis* Leedsii argenteus aureo-tinctus. If we are to have flower-pegs large enough for such names, our bulb gardens in winter will look more like cemeteries than ever. Lilies are nearly as bad. In Roozen's catalogue this autumn we have *Lilium speciosum atro-purpureum* Schrymækersi. Why need we have such names when there are already pretty combinations containing from three to six letters, easily written and easily pronounced, enough for every existing variety of Daffodil or Lily, and a thousand more might readily be invented? Surely such names as Alma, Clío, Ida, Ion, are sufficiently distinctive, and might be used for florists' varieties of each kind of flower, without fear of confusion."

It is not only those who love flowers and simple words, and have no pretension to technical or great knowledge of any kind, who groan under this pedantic tyranny. Mr. Ruskin is quite scornful about it and in a very amusing way. It is to be hoped therefore that Mr. Barr and others who christen Daffodils and other innocent children, will adopt Mr. Dod's good suggestion, and not give the pretty things ugly names.

There are many grumblings about open spaces for London, but the most striking fact about the business to me is the enormous amount of good that has been done in that way during the past dozen years or so. If we go on in the same ratio, London will be well supplied with open spaces. Much more necessary to my mind, however, at present are open streets, planted with trees, where possible; but, in any case, open and dignified, rendering locomotion from any part of the town to parks and open spaces an easy matter. At present London is wholly disgraceful in this respect; and what it is as a city can never be seen so long as the present system of close, narrow thoroughfares exists. Some of the most beautiful suburbs and some of the finest things in the east end of London are approached with such difficulty from the west end that few people care to go.

I notice an article in the *Builder* on town parks, in which the writer says that "the Paris municipality make a large and wise use of their squares and gardens to place the numerous statues they yearly purchase at the exhibition; and charming is the effect, reminding one of the gardens of Florence and Rome, and many another city in Italy—that home of the gardener's art." This is a very foolish remark. The dotting about of statues everywhere is one of the principal weaknesses in the parks and gardens of Paris, and if it goes on it will cure itself some day, as people will, no doubt, eventually see the absurdity of dotting about a quantity of stone in green gardens. The gardens at Rome, as well as the gardens of Paris, are injured by the scattering about of statues and busts. I never saw three well-placed statues in a garden in my life. It is just possible to place one here and there, and, under special circumstances, with good taste and effect. I have often seen a pretty garden spoiled with statues, and, as a principle, it is a vicious one.

Much more just is the following from the *Gardener's Magazine* :

"A vacant plot of land in Old Street is to be adorned with a granite column 33 ft. high, at a cost of over eight hundred pounds! We know the spot well. It is just large enough to nourish and display one fine Plane tree, which would cost less than eight hundred pence, and be a blessing to the dreary district. A costly and paltry monolith without meaning will not even confer respectability on Old Street."

How much is wasted in like objects in all great cities! I do not think, however, any stone scenes in them are so devoid of meaning as Trafalgar Square, and that curious stone-yard at the upper end of the Serpentine.

That it is a world of progress after all is proved by the florists offering prizes for species of *Primula*. The *Auricula*

Society intend doing this, and it is in the right direction. They also offer prizes for seedlings in the various groups. I wish they would offer prizes for the most distinct and remarkable breaks-away from their pretty circular ideals. I have often thought of the many lovely things that were lost to the world because their beauty did not allow of measurement by the narrow standard in use. How long will "florists" continue to use this absurd word, which had some meaning at one time, but not now, when any favourite flower may become the object of specialists' attentions?

Referring to growing and procuring hardy flowers, an experienced correspondent writes as follows: "During the frost I had four men wheeling rotten manure and leaf-mould on to the borders, and many are now covered 4 in. thick, and this will be forked in carefully as soon as one can work well on the ground. I think manure and shelter are the two great things in growing all flowers of robust habit. When folks grow Cabbages they use manure, but when they grow flowers they seem to think that they do not require nutriment—they are starved, in fact. The expense of hardy flowers, and the miserable bits sent out in thimble pots do much harm to the trade. I have had plants sent here to order, and they were such as I should have been ashamed to have asked any one to accept as a gift. I find it best to beg plants. I can actually beg better plants than it is possible to buy." I quite agree with this, and think that the sending out of hardy plants in small pots must give way to the better plan of good strong tufts from the open ground. There is a fortune for any nurseryman who will plant out such kinds as are wanted and who will sell them at a reasonable rate.

"It is said that the Chinese have a method of preserving Grapes during the entire year by cutting a circular piece out of a ripe Pumpkin or Gourd, making an aperture large enough to admit the hand. The interior is then completely cleaned out, the ripe Grapes are placed inside, and the cover replaced and pressed in firmly. The Pumpkins are then kept in a cool place, and the Grapes will be found to retain their freshness for a very long time." The above paragraph is "going the rounds" of the newspapers; but I wish some one would inform us how to preserve the Pumpkin.

Recently in the pages of a contemporary, a correspondent writing on Strawberry forcing, suggests that hard freezing of the plants is beneficial! One paragraph runs thus: "Now will be a good time to compare the roots of plants that have been housed some time ago, with those that have been standing out of doors, and it will also be well to note the result of the inspection, so that there will be no timidity in adopting the exposed system of wintering another year, which saves so much labour and is so beneficial to the plants." After this we may shortly expect Strawberries from the Arctic regions.

I have in my time had a good deal to do with Strawberry forcing, and though the plants have now and then had to put up with a few degrees of frost, they have occasionally told me forcibly enough, that they preferred "Jack Frost" at a distance. Many there are like them, who, though compelled to bear frost, thrive best without it; I am not sure that long exposure to a very severe frost would not do harm that could not be repaired.

JUSTICIA.

Birds and Fruit Buds.—If the present severe weather continues, cultivators must keep a sharp out-look for birds, like the bullfinch and sparrow, that attack the buds of fruit trees, as they quickly clear a plantation if left unmolested. Powder and shot is the safest remedy, but when these cannot be used, fish-jets or dusting with some noxious compound must be resorted to.—J. G.

ROSES.

ROSE HOUSE.

Pot Roses.—The buds of even the latest-flowering varieties on walls and in the most protected situations have been cut off earlier than usual this autumn; consequently, where there is at command a good supply of pot plants, these will be now more than usually acceptable. If, after the crop of buds on them when brought indoors is over, the plants of such kinds as will bear forcing are put in heat, they will make wood and produce more flowers later in the season; but there is considerable difference in the amount of heat which the different varieties of Roses will endure; for instance, the beautiful white Niphetos will not succeed well unless it has more warmth than many other of the best Tea varieties require; consequently, it should be accommodated at the warmest end of the house. Those who have plenty of stock to be introduced to heat at different times in succession through the winter, with a house sufficiently large to accommodate them, will, with a moderate amount of heat, be in a much better position for keeping up a continuous supply of blooms than where the room and plants are so insufficient as to necessitate the bloom being hurried on; for though there are many kinds of Tea Roses that will stand more heat than is generally supposed, still the diminished light during the short days of winter, any excess of warmth is sure to result in weak foliage, shoots little able to bear a full complement of fine flowers, and proportionately liable to be affected with mildew and insects. Use every precaution against the introduction to the house of aphides or red spider by dipping or syringing all plants before they are brought in with Tobacco water, in which is dissolved a little Gishurst, which latter will kill red spider with a weaker application than any other insecticide which I have ever tried. All the air that should be given for a considerable time is a very small admission near the ridge of the house, as if the atmosphere is at all chilled, or the external air brought in contact with the young foliage, mildew is certain forthwith to make its appearance; and, even with the most attentive precautions, it will from time to time attack the plants. On this account, therefore, it is necessary to subject the plants to close inspection, and apply sulphur immediately any leaves are found with the slight curl upon them indicative of the presence of the parasite. Those who have not had much experience with Rose forcing through the winter cannot be too particular in keeping a constant outlook for this worst of all pests, as if allowed to run for only a few days, it will cause the loss of probably half the leaves which the plants possess, with a corresponding reduction in their ability to flower. Roses that are planted out and trained on pillars, or on the roof, must be closely watched with the view of detecting mildew, and should, as far as possible, have their heads kept away from near where the air is admitted. All plants that have their pots well filled with roots ought to be regularly assisted with manure water. This will not only benefit the first crop of flowers which they produce, but will strengthen the growth from which later blooms may be expected. As a dark coloured variety, to mix with the light Teas, there is none that I have tried equal to General Jacqueminot, to be followed by such sorts as Duke of Edinburgh, Beauty of Waltham, Charles Lefebvre, Annie Wood, Baronne Hausmann, and Jules Margottin. Plants for successional forcing to be introduced later in the season, if in cold pits or frames, should have their pots plunged in ashes, leaves, or something that will keep the soil from being frozen, along with sufficient protecting material on and around the frames, as, in common with other plants, however hardy, their roots get injured by compression when the soil in the pots is frozen.

Roses in Conservatories and Greenhouses.—Where Roses are grown on rafters, pillars, or on back walls in conservatories or greenhouses, they should be at once pruned, before the fire-heat, which it is necessary to use to give sufficient warmth to the other inmates, has an influence in moving them into growth. If at the same time the whole of the stems and shoots remaining can be taken down and well syringed with the mixture of Tobacco water and Gishurst recommended for pot plants, it will ensure their being clear from insects when growth commences, a matter of importance, as the wood devoid of leaves will bear a much stronger application of the Tobacco water than young growth would stand. Roses planted out, as is usual, inside the house, from the limited extent of space to which their roots are ordinarily confined, are very liable to get into a weak condition, unless the soil is annually renewed as far as possible; therefore it will be much better to do this now than later, when the top growth has to draw upon the roots, rendering them less capable of bearing whatever disturbance they may be subjected to in the operation. As much of the old surface soil ought to be removed as can be done without seriously disturbing the roots, replacing it with three-fourths good sound loam added to one-fourth manure, treading all down moderately firm.

T. BAINES.

Propagation of China and Fairy Roses.—These Roses are easily propagated, and those who may wish to work up a stock of them need experience no difficulty in so doing. Cuttings should be taken about the middle of July, cutting them to two joints, and inserting them so that only the uppermost eye and leaf are above ground. Make the soil—which should consist of a mellow mixture of leaf mould and sandy loam—as firm as the hand can press it, and give a good watering when the work is finished. Then put on the lights, and keep the frame quite close for two days, after which time the lights should be regularly removed on fine, still nights; or, if the weather should be stormy, with heavy rains, tie them, and allow them to remain so day and night. The main point to be observed is to guard the cuttings against the desiccating influence of the hot summer's sun, whilst at the same time avoiding anything like undue confinement and deprivation of light. This result is best attained by placing the frames close up under a north wall, where but little shade will be necessary, and where the atmosphere is at all times more or less cool and moist. As soon as shade can be withdrawn, open the frames and gently syringe the cuttings, leaving them fully exposed to the refreshing influence of the cool night air. This treatment will preserve the foliage green and healthy. By the beginning of the autumn quite 95 per cent. will have taken root, and if protected from severe weather during the winter they will be in first-rate condition for planting out in the spring. By the beginning of March a piece of ground should be well stirred and manured, in which the young plants may be planted some 9 in. apart, when, if copiously watered in hot weather, they will make healthy robust plants by the end of the season. The China Rose is one of the most floriferous varieties that we possess, and the flowers are so useful for cutting that any spare and suitable situation might be profitably filled with them. It is also one of the best kinds for forming a Rose hedge. The Fairy Rose is well suited for pot culture, its neat compact growth and floriferous nature rendering it valuable for forcing purposes. Good strong plants potted now may be introduced into gentle heat at the commencement of the new year, and will come nicely into bloom at the time when Roses of all kinds are very scarce.—J. CORNHILL, *Byfleet*.

Gloire de Dijon, Cheshunt Hybrid, and other Roses for Forcing.—It seems to be becoming a race between *Maréchal Niel* and *Gloire de Dijon* as to which is to be the most popular greenhouse Rose. The *Maréchal Niel* has undoubtedly the advantage in some respects, but *Gloire de Dijon* is the surest grower either on its own roots or grafted, and the flowers when developed under glass are hardly inferior to those of the other. It has a habit, too, of flowering longer. The popularity of this Rose is shown by the quantity of it which is propagated by the great Rose growers. One noted nurseryman in the south informed me that he grew 20,000 of the *Gloire de Dijon* alone. At the Handsworth Nurseries, near Sheffield, I saw lately a houseful of young plants of it in 9-in. pots, and about 10 ft. high—all for forcing purposes. As to the *Cheshunt Hybrid*, it is the best red Rose for planting out under glass with which I am acquainted, being a strong grower and climber, and a free bloomer, producing flowers abundantly in early spring and less or more at all times during the season. Can any of your readers tell me to which class this Rose belongs? It is called a "Hybrid," but it is classed among the "Teas," and was first exhibited as such by its raiser, if I am not mistaken, but it is not Tea-scented, nor like a Tea in flower. Nevertheless, it is a fine Rose. Another useful kind as a variety is *Souvenir d'un Ami*, also a good forcer or greenhouse Rose, blooming more or less nearly all the year round if it has heat enough in winter, and the flowers are large and of good substance. Nor must our old friend *General Jacqueminot* be forgotten as a forcer; for early or late work it is still unsurpassed, as it forces better than most others, and opens its buds freely, and its colour is always good. There are, however, but few of our early and free-blooming Roses that do not force freely, and if they are not pushed hard till after the New Year or February they yield plenty of fine flowers.—J. S. W.

China Roses.—Why is it that the old blush and crimson China Roses are not more extensively grown than they are? They flower in succession without a break from June to November, and possess the most pleasing colours to be found among cultivated plants. They grow and flourish in soils and positions in which the Hybrid Perpetual Roses would be starved out of existence. At *Gunnersbury Park* Mr. Roberts planted several hundred last spring in the shrubby borders, and no other plants in the same borders have proved so effective as these common Roses.

Rose Beds at Goodwood.—I can fully endorse your remarks (p. 529) in reference to pegging down Roses. Three years back I was called upon to replant an old Rose garden, and I introduced these Rose beds round the outside, which I am pleased to say proved very satisfactory. The individual blooms are much larger, and the plants more robust than those under any other system of culture.—R. GILBERT, *Buryhley*.

THE FLOWER GARDEN.

STANDARD PELARGONIUMS.

GRAFTED Pelargoniums, such as those recommended by "A. D." (p. 459) are very interesting and useful for the decoration of the greenhouse. The Ivy-leaf and other varieties mentioned seldom, however, remain long in a healthy condition when grafted upon zonals; such, at least, has been my experience with them. Standard zonals, however, have been long and extensively grown here for the decoration of the flower garden, and the diversity of colour furnished by the flowers of these plants is so great, ranging, as it does, from the purest white to the most intensely bright scarlet, many of the intermediate shades being also exceedingly beautiful, that they are altogether better suited for the purpose of planting in the centres of large beds, or in association otherwise with ordinary bedding plants than standard Roses, which are sometimes used for that purpose; but, unfortunately, however beautiful they may be, they are generally past their best at the time when bedding plants are in their greatest beauty, a circumstance which consequently mars the general effect of the garden. As regards standard zonal Pelargoniums, this is certainly not the case, inasmuch as they remain in full bloom from the time they are planted out until it is necessary to remove them to their winter quarters, which need not be earlier than the middle or end of October. The circumstance of growing these plants in the form of standards, appears to increase very considerably the production of bloom, a result which may possibly be ascribed to a certain amount of restriction which they experience in the supply of nourishment from the roots. Indeed, it has been a matter of astonishment to many how such slender stems are able to convey the necessary amount of nourishment to such large, floriferous, and robust heads as those with which they are furnished. Considerable numbers of these plants have long been grown here, and some of them are at least ten or twelve years old, but they are still in excellent health, and annually produce what is considered a very remarkable and good effect in the flower garden during the summer months. The plants used in this way are all seedlings, as such are found to be better suited for the purpose of forming standards than plants raised from cuttings. The seed is sown early in the autumn or as soon as it can be obtained, and the young plants are planted in lines in May following in ordinary garden soil. They are generally in flower by the middle of July, when those intended for standards are selected, and this selection is of course influenced by what may be considered a suitable habit of growth in individual plants, desired colour, and quality of flowers, &c. To such plants a straight, strong stake is supplied, and to this the principal stem is secured, and all other shoots are stopped or cut back, so as to encourage as much as possible the development of the main or principal shoot. Such plants are carefully lifted and potted in the autumn, wintered in a warm greenhouse or similar structure, and again planted out during the following May. And by the end of this, the second season, they have generally attained the desired height, viz., 4 ft. 6 in. When the main shoot is stopped, the lower side shoots are neatly cut off, and the plants are encouraged to form well balanced and symmetrical heads. In autumn they must be again potted, using for the purpose comparatively small pots. They are then placed in a growing temperature until they have recovered from the effects of their removal from the open border, and have become well established in their pots. Treated thus, they will generally be found to be sufficiently developed to take their place as standards in the flower garden during the following or third summer, and, with proper treatment, will, as has been stated, last for many years.

The shoots of the zonal Pelargonium are well known to be somewhat brittle, and are liable to be broken or injured by high winds unless they are well secured by stakes, and a prominence of these necessary supports are apt to detract from the graceful appearance of any plant, however beautiful its flowers and foliage may be. In the case of these Pelargoniums, however, only one stake to each plant is employed, and they are formed of $\frac{3}{4}$ -in. iron rod, $4\frac{1}{2}$ ft. long, furnished with a tripod some 15 in. long, to insert in the soil, as close to the stem of the plant as it can be got without injury to the roots. The stems are secured to those roots which are threaded at the top, so that an iron hoop or ring, 2 ft. in diameter, formed of $\frac{3}{4}$ -in. rod, strengthened by two cross bars, can be fixed by a nut to the head of the iron stake, and which can, of course, be removed at pleasure. To this hoop the shoots are carefully tied as they are produced, and both stakes and hoops are painted green, so that they are not conspicuous, and the hoop is very soon altogether hid by the foliage. The large globular heads, which are soon formed, generally attain dimensions exceeding 4 ft. in diameter, and the highest winds inflict no injury upon them whatever. Towards the middle of October, or before they are likely to be seriously injured by frost, the heads of the plants are cut tolerably close in, the iron stakes and hoops are

remove, and the plants are carefully potted. The somewhat heavy heads are supported by strong wooden stakes, and the plants are placed for a time in gentle warmth, until they have become established in their pots, and give indication of commencing growth.

It is found that the smaller the pots into which the roots of the plants can without injuring them be got, the better the plants generally succeed during the winter. Young shoots are apt to be produced upon the stems during the first year or two, but these are rubbed off as they appear, and as the plants become older this is seldom required. Objections have been made to the practice of training the zonal Pelargoniums in the form of a standard, being, it is alleged, contrary to their natural habit of growth, &c. This argument, however, equally applies to many other species of plants so treated; therefore I will attempt no defence of the practice, further than to say that, in growing them in this manner, an effect can be produced which many have admired, and which it would be difficult to accomplish in any other way.

P. GRIEVE.

Culford, Bury St. Edmunds.

SHRUBBY AND HERBACEOUS SPIRÆAS.

ONE of the most suggestive things I have ever seen in a garden was a group of these plants, both shrubby and herbaceous, in the late

Group of herbaceous and shrubby Spiræas.

Mr. Hewetson's garden at Weybridge. The shrubby species, among which was *Spiræa arifolia*, were towards the centre, and the herbaceous ones grouped around it, and the effect of the combination was singularly beautiful, especially as it occurred in a picturesque spot. It was also a much more natural combination even, speaking in what might be called the technical or scientific sense, than any idea ever seen carried out in a botanic garden. The engraving, though a delicate one, fails to show the right effect owing to a difficulty of showing the immense number of blooms of the white-flowered shrub *Spiræa arifolia*.

The Horned Poppy.—In the Horned Poppy (*Glaucium corniculatum*) may be found a plant of considerable usefulness for winter decorative bedding, as it is quite hardy, and has very handsome ornamental foliage of a silvery hue, almost as white as that of the *Centaurea*. The leaves are much more deeply cut than those of that plant, and, planted closely together, make either an effective mass or very pleasing lines. To ensure strong plants for the winter, seed should be sown about May, as the plant is a biennial, and should be treated as such. When in bloom it makes a striking border plant. —A. D.

NOTES ON HARDY PLANTS.

Geranium Wallichii.—We have found this to be a very useful plant, and one which flowers continuously. Its habit is sprawling; but in some positions this is an advantage. The flowers, which are large and pale blue, have dark veins. It comes true from seed, which is the way to increase it; division need not be attempted.

Anthemis arvensis fl.-pl.—Cut down for cuttings, this is now (Nov. 29th) again in flower, and it will go on blooming if the weather be not too severe. This old plant was picked up a couple of years ago in a miner's cottage garden at Penicuik, and reintroduced to those who had grown it many years ago. It is also cultivated about Kilsyth, in the neighbourhood of Glasgow. Lasting, as it does, any length of time in water, its flowers being perfectly double, and pure white, a colour which contrasts well with the dark green feathery foliage, it is a plant that deserves extensive cultivation.

Venidium calendulaceum.—One as seldom sees this as the invaluable pot Marigold grown as an annual. It was this season in flower in May, and continued until the sharp frost (9°) in October put a stop to it. There is considerable diversity in its seedlings, both as regards habit and the size, shape, and shading of its beautiful orange flowers, which open and shut when cut as regularly as when growing in the border. Careful selection in seed saving is needful in order to secure the best forms of this delicate and refined Marigold, as I have heard it described. I observed that Mr. Joad had a plant of it in the bed of one of his houses, and he is of opinion that it is perennial. Certainly to continue its blooming by growing it indoors would be desirable.

Polygonum cuspidatum.—I should like to add a word of warning to the description of this plant (p. 452). It should never be planted in a border that is annually dug, as the smallest portion of its running roots grows, and it is certain to become a pest equal to *Campanula rapunculoides* and variegated Gout-weed. A border of herbaceous plants 56 yards in length is ruined here by these three pests. The *Polygonum* has also got among the roots of Rose bushes, and never can be eradicated. Its arching branches coming through those of *Madame Plantier* and *Celine Moss* are picturesque perhaps, but turf is the safest position for such a deep strong runner. In spring the young crimson shoots are very ornamental and useful for cutting, and we always wait until it has grown out of the red state before commencing our annual rooting out of the three pests just alluded to. Mr. Salter told me the roots were edible and used as food in Japan.

Thalictrum minus and *T. adiantifolium* are considered synonymous, but there is one striking distinction, viz., *T. minus* runs and *T. adiantifolium* does not. One plant of *T. adiantifolium* came originally from Regent's Park. We find that it does not come true from seed which it ripens freely, and therefore we retain the original true form by means of division. Desirable for foliage as are all the small-growing *Thalictrums*, *T. minus* (I mean the wild plant) has to be watched, as it is a serious matter when the tough roots get among Tea Roses or plants which one cannot lift at any moment.

Saxifraga Wallacei.—Mr. George Wallace, of the Dean Cemetery, the raiser, three years ago, of this distinct *Saxifraga*, which is by some considered to be very like *S. Mawii*, told me two strong points of difference between these two sorts; his seedling, he declares, never forms bulbs as does *Mawii* at the axils of the leaves—what at first sight appear look like bulbs forming, stretch out into branches in *S. Wallacei*, and for winter this is more useful than *Mawii*, as it does not die down like that kind, which springs up from the crown each season. The two plants are quite distinct, and should both be grown.

Cineraria maritima.—This, I see, is recommended for winter bedding, but *C. acanthifolia* is a much more reliable plant, being perfectly hardy and of very stiff, firm growth, bearing snow or wind with impunity. We have symmetrical plants of it alternated with worked Ivies and variegated *Iris foetidissima*, 1 ft. high and 1½ ft. through. We cut these *Cinerarias* down in June, and they at once spring up again thick, and form fine grey specimens from which we get any quantity for our flower-glasses all winter without disfiguring the plants. For draughty entrance halls or passages it is excellent, and, of course, when indoors it is much more silvery, as it is always dry.

Variegated Iris.—We have a large quantity of this, which we used when winter bedding was our strong point, and I would gladly exchange it with any one who is busy with winter gardening, and who wants a pointed-growing variegated plant, as I cannot cast away so useful a subject, and yet we need the ground on which it grows.

Carex japonica variegata.—I do not see this in the lists of plants given for winter beds; it is, nevertheless, a most satisfac-

tory plant for such a purpose, perfectly hardy, and of graceful outline.

Chrysanthemum frutescens.—The severe frosts which we have had have finished half-hardy plants; but this *Chrysanthemum*, which frequently stands the winter here, and the yellow form which we have grown without a name for more than twenty years are both untouched. One variety is a fawn-yellow, not the least primrose, and valuable for its very scarce shade of colour. It is of weaker and thinner growth than the white, so that in planting out we set three yellow for one of the white kind. It is, however, a pity to cry up one plant at the expense of another; both should be in every mixed border, possibly all three, but the Primrose form we have not here. The blue-green foliage of white *Chrysanthemum frutescens* is most attractive in the borders at this season, and useful for cutting. It is grown in abundance for the Paris markets; "I heard of the fawn-coloured *C. frutescens* at Nice," a resident there exclaimed on seeing it in our borders.

Pine-apple-scented Salvia.—This is not killed yet; it is called *elegans* about here, but at Mr. Joad's garden I seen quite a different plant under that name, and the Pine-apple was merely labelled sweet scented, and had come from Mr. Green thus designated.

Lobelia fulgens.—This is quite unharmed as yet. I saw at Folley and Staunton-on-Wye (Herefordshire) a bed of *L. cardinalis*, which had stood without protection, save that of the snow, last winter. At Folley also *Berberidopsis corallina* and *Fabiana imbricata* on the house wall had stood unprotected and unharmed.

Wardie Lodge, Edinburgh.

F. J. HOPE.

A FINE SUB-TROPICAL BED.

ABOUT the middle of October, I paid a visit to a friend living in the south-eastern part of Kent who takes the greatest interest in his garden. At the back of his house is a long lawn with an undulating bank on either side judiciously planted with ornamental shrubs and trees; in one of the recesses was a bed of very fine Castor-oil plants, and Chinese Rice-paper plants, which notwithstanding the cold and wet summer which we have had, were in first-rate condition and most effective. With the smooth turf in front and the shrubs behind, the group stood out grandly. I was much surprised to learn with how little trouble and expense this fine effect had been produced, the plants whilst under cover never required a space of more than 20 square feet; had the same bed been planted with ordinary bedding plants, the attendant expense and labour must have been much greater, and the effect to my taste much less. Of this bed I obtained the following notes from my friend, thinking they might prove of interest to some of the readers of THE GARDEN.

"The garden was laid out by Mr. Gibson about ten years ago, and shows what can be done with the aid of a skilled garden architect and without a large outlay of money. About five acres of ground were purchased at the back of a good sized semi-detached villa residence within an easy five minutes walk of a town of over 20,000 inhabitants; there were natural advantages in a landscape point of view, but they were so utilized as to make the surrounding property look as if it belonged to the same owner. The general exclamation of friends on seeing the bed in question, has been 'how very handsome, so large, and in this wet year too, but we could not attempt anything of this kind, it requires too much glass.' Well, let us see. The bed is curved in shape, it is about 27 ft. or 28 ft. long, and not quite 6 ft. in width, it faces S.E., and is on a slight artificial slope on the inner curve of a small shrubbery. The soil of the bed is from 15 in. to 18 in. in depth, and is replenished every spring with a little rotten manure and half rotten leaf mould, and it rests on a little over 2 ft. of brick rubbish. The Castor-oil plants this season varied from 4 ft. 6 in. to 7 ft. in height, and they consisted of the tall and short growing sorts of both the red-leaved and green-leaved varieties judiciously mixed; there were in all about thirty, and about an equal number of the *Aralia papyrifera*, the latter forming a row in front, and one or two were planted behind the row, just to break the formality of a line. The *Aralias* were over 2 ft. in height.

"The management of these plants would not tax the resources of any ordinary garden where there is a glasshouse or two and a glazed pit, and also the command of a little bottom-heat. The Castor-oil Beans, which germinate very rapidly in a little bottom-heat, were sown in small thumb pots as late as the first week in April, in a small hothouse, but not in bottom-heat; three or four days after they had been shifted into small 5-in. pots, they were removed to a sheltered part of a greenhouse, and then on to a glazed pit, and they were turned into the bed out of 6-in. pots towards the end of June. When the frosts of the previous autumn had destroyed the beauty of the *Aralias* which had been planted out, and had killed the tops, a few of the quill-like roots were dug up and placed in seed pans in

the hothouse; more plants sprang up than were wanted; the best were planted in small thumb pots, and left for six weeks or more in the hothouse; after which they were shifted into slightly larger pots, and placed in the greenhouse, and treated in the same way as the Castor-oil plants, except that they were turned out of 7-in. pots into the bed. During the whole of this time the plants did not require more space than the pots which contained them.

"In a hot season a bed of this sort would require an occasional watering to soak into the soil. There is really no more trouble than with ordinary bedding stock which has to be saved through the winter, and there can be no comparison as to beauty between the handsome foliage of the sub-tropical plants and the flat bed of colour, however fine, which is oftener than not damaged by rain just at the time when the garden is wanted to look at its best." G. S. S.

HARDY v. TENDER PLANTS.

UNDER this heading there are some remarks (p. 504) which I do not think ought to be passed over unnoticed, because comparisons are there made that are not only in bad taste but positively misleading. An injustice, too, is done to cultivators and owners of choice plants. The writer of the remarks in question must either be drawing upon his own imagination or he places a low estimate upon the tastes of the horticultural public. He says that *Coleus Verschaffelti* would still be much admired if it cost a guinea a plant. Now he says it is disregarded because it is common. The fact is, this *Coleus* is the only one that has been extensively grown, just because it is easily managed, and the only one that succeeds as a bedding plant. There are few gardens without it, and it is extensively grown in our public parks and gardens because it is cheap. The remarks about *Gardenia florida* are not very obvious, but when its culture is understood no plant is easier grown, and most persons believe that it is not inferior to a good Pink, but its comparison to a Rose is out of the question. Then we have I think most injudicious comparisons between Orchids and hardy plants. I have grown and admired hardy plants for at least a quarter of a century; but the idea of comparing *Calanthe Veitchi* with a Snapdragon is too much. Snapdragons are beautiful hardy plants for the cottagers' garden, or any garden for that matter, but they never flower at Christmas, while *Calanthe Veitchi* gladdens us with gorgeous spikes of rose and crimson flowers at that dull and dreary season. *C. veratrifolia* is, we are told, inferior to a good white Phlox, and that it would be positively insignificant in a herbaceous border. I really cannot understand how a person having the least knowledge of plants can make such a statement. If *Calanthe veratrifolia* could be grown in a herbaceous border as it can be grown in an hothouse, it would stand out pre-eminently as one of the most beautiful of plants. Comparing it with a white Phlox is absurd. *Calanthe veratrifolia* has flowers of snowy purity, and they last in beauty for three months, and in a cut state they can be used for purposes for which no one would dream of using the Phlox.

The intrinsic beauty of flowers cannot be measured by pounds, shillings, and pence; their commercial value must always depend on their rarity and beauty combined. Many new and rare Orchids are introduced annually, but all Orchid growers are well aware that they do not fetch a high price merely because they are rare, but because they are beautiful as well. Mr. Stevens, of King Street, Covent Garden, could tell us something about the value of Orchids when growers have found out their intrinsic worth. Collectors, too, soon find out to their cost that it does not pay to introduce plants of any kind that have only rarity to recommend them. I will not continue my remarks further, except to say that the most outrageous taste is displayed in reference to the *Bougainvillea*. That hardy herbaceous plants have been sadly neglected there can be no doubt; that there is now an equally strong feeling in their favour cannot be questioned; and if we are indebted to one periodical more than another for bringing about this better state of things it is THE GARDEN. But there is one fact that must not be lost sight of, and it is this—herbaceous and hardy plants claim a place in the flower garden, but if pushed into a position which they cannot worthily occupy, and if unjust comparisons are made between them and other beautiful flowers, no good can come of it. Let all things come in their proper order. Let there be a place for all, and every one to its place. J. DOUGLAS.

Osborn's Golden Feather.—I find that this kind having a denser and more compact habit of growth than the commoner sort, withstands the winter best. This may be a matter of little moment to those who only use these plants the first year raised from seed, and then throw them away; but those who use them for winter effect, and especially those who grow them in quantity to seed the

second year, find it to be a matter of the first importance that they should possess the hardiest kind. Osborn's lacinated variety is, perhaps, somewhat less bright in hue, but its foliage is the most pleasing; and a subdued yellow is certainly much more acceptable under brilliant sunshine than a glaring gaudy tint like that furnished by a mass of the common kind.—A. D.

TOM THUMB FUCHSIA.

THIS is a pretty little plant, somewhat resembling *F. gracilis*, but smaller, rarely exceeding 1 ft. in height, and forming spreading little bushes from 12 in. to 18 in. in diameter, each tiny shoot being laden with crimson-sepalled, purple-petalled flowers and bright buds, as suggested in the annexed engraving, which represents the top of a flowering shoot, exactly of the natural size. The plant does not appear to be generally grown in England, but here, in Ireland,

Tom Thumb Fuchsia.

the naturalised home of the Fuchsia, it is more common, although nowhere so plentiful as the *F. globosa*, *F. Riccartoni*, and *F. gracilis*. Little bushes of it are charming ornaments to the rockery and herbaceous border, or even for isolated positions on the lawn in sheltered places. Cuttings inserted in any light garden soil about July, and sheltered by a hand-glass or cloche, root freely and form pretty little plants for flowering the following year. As a pot plant it is very desirable, and if cuttings be forwarded in a cold frame pretty little specimens may be obtained, and are very useful for summer and autumn greenhouse or window decoration. Were it more readily procurable, it would prove to be a most desirable plant for the cottage window. Whether this Fuchsia is a puny form of the hardy *F. Riccartoni*, or a pure species hitherto overlooked in the great struggle after "new and rare" plants, is a question of merely secondary importance. The main point is that it is one of the most distinct and effective of all hardy kinds of Fuchsia, and as such worthy of a far more general distribution than it now enjoys. Nevertheless, if any readers of THE GARDEN will be good enough to tell me the correct name, or any details as to the introduction or history of the plant which may be known to them, I have no doubt

that such information would be welcomed by many others besides myself. Meanwhile I will content myself with its popular name, Tom Thumb Fuchsia.
F. W. B.

Winter Bedding with Evergreens.—Some excellent suggestions on this matter are given in THE GARDEN (p. 451). Evergreen winter bedding must soon become more fashionable than it has hitherto been, but the difficulty which many will experience in securing sufficient and appropriate plants for the purpose will, I fancy, debar many from practising the system so extensively as they might desire. For several winters we have filled our flower beds with evergreens in a manner which has pleased everybody, and the plan can be so easily carried out that I am sure anyone who may give it a trial will find it to answer the purpose. In most gardens there are large plants of various kinds of evergreens, which generally require cutting in at this season, and these prunings, when effectively arranged in beds, with their cut ends in the soil, produce such an evergreen flower garden as few rooted plants could surpass. We have just finished filling our flower beds in this manner; some of the beds are filled with little shoots not more than 6 in. high; others have large little-tree branches of finely-berried Holly dotted here and there above the dwarfier material. Some of the circular beds have a finely-shaped well-berried Holly-top as a centre, others have a small Spruce point placed amid other kind of evergreens. Dark berried Holly twigs border a light centre of the same kind and *vice versa*. Any kind of arrangement may be adopted that will suit the beds. If put in now we find that nearly every kind of evergreen will remain fresh far into the spring; or, indeed, until various kinds of bulbs begin to make a display. When the winter has been mild we have often found many of the twigs put in in autumn little rooted plants in spring. At p. 451 mention is made as to the "facility" with which the plants there recommended can be "transplanted;" but I venture to think that should a severe winter follow the transplanting of Hollies and various Conifers at the present time many of them would be likely to suffer severely, especially in the hands of the inexperienced; and I fear there would be a good many deaths during a hot summer were the plants only transplanted at the beginning of it, as they would be where the plants are cleared out to make room for the summer bedders. If rooted plants must be used bushy little plants in 6 in. or 8 in. pots would be best for the purpose. Two or three hundred would fill a good many little beds, and plunging the pots would be as easy a matter as planting, while the chances of being killed through bad planting or weather influences would be removed.—CAMBRIAN.

Extremes of Cold.—At a meeting of the Royal Botanic Society held on Saturday, Col. Platt presiding, the secretary reported the extremes of cold during the month. Skating in the gardens so early in the winter has not been known for many years. Mr. G. J. Symons, F.R.S., reminded the Fellows that there had not been a warm month for two years, and that every month since August, 1878, had been colder than the average. Besides being so cold, the period had been characterised until the end of September, 1879, by a most unusual deficiency of sunshine and excess of rain. The mean temperature of December, 1878, and January, 1879, were remarkably low, and yet the winter of 1879-80 has begun with lower temperature than its precursor. The actual minimum temperatures in the neighbourhood of London had been surpassed in intensity on some previous occasions—for instance on Christmas Day, 1860, and again on January 4, 1867, the temperature of the air at Camden Square fell to 6.7°, and the Christmas Day, 1870, to 14.0°, while this year the lowest point was 16.1° on the morning of December 7. The greatest severity of the late frost was, however, felt further north than London, and temperature below zero—i.e., more than 32° below freezing, had been reported from accurate instruments in many parts of the country.

Half Hardy Plants and Frost.—The present severe frost, following so hastily on a wet sunless summer, will undoubtedly affect many plants that are usually hardy enough to withstand an ordinary winter, when their growth is well ripened by summer heat; but this year the finest and most growing weather which we had was late in the autumn, consequently vegetation was active even until suddenly checked by severe frost. There is one point on which I would warn the inexperienced, and that is, that when thaw comes not to be in a hurry to clear away the withered foliage from such plants as Pampas Grass, Tritomas, or any border plants of similar habits, as from my own experience I know that these natural protectors, viz., dead leaves, are best left intact until all danger of severe frost is over. We all like to see our gardens look neat and trim, but when the life of our plants is at stake, it is better to tolerate a little unsightly rubbish than to leave our garden full of blank spaces for the rest of the year; even a handful of leaves placed around a plant may sometimes save its life.—J. G., *Linton*.

THE GARDEN FLORA.

PLATE CXXI.—A GROUP OF BEARDLESS IRISES.

Drawn by CONSTANCE PIERREPONT.

EVERYONE knows and, knowing, admires the bearded Irises; but it is not everyone who is aware of the beauty and the delight which may be found in the beardless Irises, a group of which is represented in the plate issued with the present number. In this, as in so many other instances, the popular judgment is founded on reason. Taking them all through, no beardless Iris, not even the Kämpferi (the one beardless Iris which has been honoured with the title of a "florist's flower," and which was described and illustrated in No. 406, p. 198) possesses that union of grace of outline with delicacy of colouring, which is the charm of such a bearded Iris, for instance, as *I. pallida*. Yet many of the beardless Irises are handsome and indeed lovely, and they are all worthy the attention of those who love flowers as flowers, and who do not regard plants merely as material for constructing the gaudy or the grotesque patchworks sometimes spoken of as gardens. To the gardener who is also a botanist they have an especial interest, because they are not only much more widely spread than the bearded forms, but in all probability older, that is, earlier in origin.*

Not only are the recognised species belonging to the beardless division more numerous than those of the bearded, but the differences between the several kinds are much more marked and distinct. The bearded Irises are very much alike, and, in giving them separate names, stress has often to be laid on such variable characters as colour and size. The beardless Irises, on the other hand, present a large number of tangible unlikenesses, enabling the very beginner to recognise the differences between the several species. Numerous, however, as are the various kinds, a very little study shows that they may be arranged with more or less completeness into a number of groups, each consisting of central or typical and outlying members.

One group, of which the beautiful unguicularis (or *stylosa*) may be taken as the type, is not represented in the plate, for the very good reason that the members of this group flower in winter or quite early spring, whereas most of the beardless Irises and all those pictured in the plate flower in mid or late summer. I regret this unavoidable omission, because unguicularis is, perhaps, the most lovely of all the beardless forms. Possibly its beauty appears all the more striking, at all events we appreciate it the more, just because it comes to us in the winter. It is an excellent, easily-managed pot plant, flowering readily under glass (in the open it is apt to be cut by the frost), and I would strongly advise those who are the happy possessors of a little greenhouse to obtain from Messrs. Barr & Sugden, or from Mr. Ware, or from some other of the nurserymen who make a speciality of Irises, good, strong, sturdy specimens of this delightful plant, taking care to choose those with the pots crammed full of roots. I think they will not be disappointed. The flowers are not very numerous at a time, but they come in succession; I had last winter a plant which went on flowering from the beginning of December to the end of February, right through that memorable dreary season. Its large and elegant lavender coloured flowers, which, whenever they felt the influence of a little warmth and sunlight, sent forth a delicate and delightful fragrance, brought me consolation on many a dark and dismal day. I well remember that before the Iris flowered

my little greenhouse was nearly filled with Chrysanthemums, of whose bloom I, and especially my gardener, were not a little proud; but as soon as my first unguicularis bloom had opened I was impatient until my Chrysanthemums had been cast out: its delicate and sweet beauty made me intolerant of the showy, but, compared with it, garish florists' flowers.

A very distinct group is formed by *I. spuria* and its allies. These are, for the most part, tall plants, blooming somewhat late in summer, with erect, rather narrow leaves and close set flowers, and their ripe capsules are strongly ribbed. One of the handsomest of these is *I. ochroleuca*, No. 6 in the plate. The opaque waxen whiteness of its large petaloid stigmas,* closely bent down, as in all the members of this group, over the falls, gives a peculiar charm to the flowers, contrasting as it does with the rich yellow of the falls themselves. The origin of *ochroleuca* is unknown; it exists, as far as is known at present, in gardens only. A variety with the name *gigantea* is highly spoken of. One disadvantage in this group is that the flowers are so close set on the stalk that they have not room to expand, and, as shown in the figure, are tilted up on one side. A gathered cluster makes, however, a very handsome centre in a nosegay; and, as is the case with almost all Irises, the buds expand readily in water. Next to *ochroleuca*, perhaps even surpassing it, comes the allied *I. Monnieri*, a very tall plant coming from Crete, with abundant large flowers of a rich yellow colour. It is one of the latest flowerers, showing a full bloom even when *Kämpferi* has passed away, and has the further merit of being fragrant. The odour is not very powerful but very pleasing. Very closely allied to these is the Himalayan form, *I. aurea*, No. 8 in the plate. This is a very handsome plant, with which I hope soon to become better acquainted than I am at present. *I. spuria* itself, with its many varieties, does not recommend itself to me very greatly. In some of the forms, as in the so-called *spuria major*, and also in the Algerian variety known as *Reichenbachii*, the colouring is bright, and some people might think them handsome, especially when seen in masses; but the mixture which they offer of blue or purple and yellow is to my mind too coarse to be pleasing; besides, there is a certain stiffness and want of elegance in their outlines. I prefer the smaller flowers of such varieties as that known as *desertorum*, with its paler flowers, narrow falls, and, in some cases, marked fragrance, or even the white *Güldenstädtii*, which, however, is very inferior to *ochroleuca*. Some of the *spuria* group are absolutely worthless from a gardening point of view. When you have devoted the best nook in your garden, and unwearied attention to a plant which, in the end, bears, amidst a dense mass of tall, strong leaves, a number of insignificant dirty-coloured flowers, you begin to understand the meaning of the phrase "of botanical interest only." As an outlying member of the *spuria* group, I may refer to the little *I. graminea*, though this is by some authors associated with quite different

* It may, perhaps, be worth while to remind the reader that the flowers of the Iris consists of the following parts: On the outside are the three outer petals or divisions of the perianth, which, since they generally hang or are bent down, are called "falls." Within these, and alternating with them, come the three inner perianth divisions, which, since they are generally erect, are called "standards." In the centre of the flower the style splits up into three stigmas, each of which, broad, highly-coloured, and petal-like, spreads out and hangs over, or sometimes is closely bent down upon the fall opposite to which it is placed. Each stigma terminates in two triangular, often-toothed, sometimes large, sometimes small, flaps, the so-called crests, well shown in many of the figures of the plate. The stigma, in overhanging the fall, gives rise to a sort of tunnel, sometimes with a wide, sometimes with a narrow, mouth, and on the outside of the stigma, at the base of the crests, just at the mouth of the tunnel, is a narrow ledge. It is on this ledge that the pollen must fall to fertilise the plant. Inside the tunnel, lying underneath each arching stigma, sometimes readily visible, sometimes almost entirely hidden, is an anther. All Irises have markings on the fall just at the mouth of the tunnel, for the purpose, apparently, of attracting insects; and the insect, a bee for instance, in entering the tunnel for the purpose of sucking the nectar at the bottom of the stigma and fall, brushes against the ledge of the stigma, and deposits on it the pollen which he has gathered from another plant. The beard of the fall, which leads from the surface of the fall right into the tunnel, seems to be a device for compelling the insect to brush against the ledge.

* I must not enter into this point here, but there are many reasons for thinking that at the curious tuft of hairs on each of the three outer petals or "falls," which we call the "beard," is a comparatively late introduction, the first Irises which came into existence being, in all probability, plain beardless ones.

A GROUP OF BEARDLESS IRISES

kinds.* This is of no great value as a border plant, the flowers are too much hidden by the over-topping leaves, and the flowers themselves are singly of no great beauty. Nevertheless their mixed blue and purple tints will be found to render them of value as cut blooms; they can then be made to harmonise most effectually with other flowers.

Next to *I. Kämpferi*, with which the present paper does not propose to deal at all, the most popular, and, on the whole, the most beautiful of the beardless division, are the members of the sibirica group. In the typical form, *I. sibirica*, the flowers are, it is true, small, but they are produced in unstinted profusion, and their colouring and marking fully atone for the want of size. Many seedling varieties of sibirica of divers colours and tints are to be met with in the nursery-men's lists, all of them beautiful, some of them exceedingly so. The great feature in all of them is the delicate veining and marbling of the falls, as indicated in the white variety represented as No. 5 in the plate; but it is impossible in any lithograph to reproduce the tints and gradations which make up the charm of the living flowers. All these kinds are worthy of cultivation; the only one to be avoided is *I. sibirica* fl. -pl. † Besides the garden varieties, there are many kinds of natural occurrence, such as the form known as *acuta*, with comparatively short flower-stems, and *flexuosa* with white flowers; and stretching away from the type are forms which may be recognised as distinct species. Messrs. Barr & Sugden are distributing a charming plant of this group, with pale and with also deeper purple flowers, under the provisional name of *trigonocarpa*; and Haage & Schmidt have a kind which they call *tenuifolia*, ‡ possessing the desirable feature that the flowers emit a perfume like that of cloves. But the one kind which "no garden should be without" is the form known as *orientalis*, No. 4 in the plate, the flowers of which are larger, the falls broader and bigger, and the colouring more intense and deeper than in *I. sibirica*. The red sheath or spathe, moreover, gives the plant a beauty while it is still in bud; few sights are, indeed, more charming than a well-grown plant of *orientalis*, with its flowers partly expanded and partly ensheathed as buds.§

I have not yet had an opportunity of studying as closely as I could wish *I. tenax*, a North American form (No. 2 in the plate), but it is obviously a close neighbour of *sibirica*, and is a very desirable plant; it is now being carefully cultivated and may be obtained from the leading firms.

Allied to *tenax*, on the one hand, and, in many of its features, to *orientalis* on the other, and yet forming the centre of a group of its own, is the Californian form *I. longipetala*. This, the various cultivated specimens of which appear to vary not a little, is a showy plant; but its rather long and straggling falls, in spite of their charming light violet or lavender colour, and their graceful markings, give it a more or less unfinished look. ¶ Closely resembling *longipetala* in its foliage and habits, is the form which Regel has introduced under the name of *I.*

* The form of the flowers, especially the stigma firmly reflexed over the fiddle-shaped fall, the ribbed capsule, the characters of the roots, and other features are most distinctly those of the spuria group, in spite of its leaves being, especially in the narrow-leaved form, narrower than the other members of the group.

† If any "double-minded" florist wishes to have brought home to him the evil he is doing by his efforts to "double" flowers which Nature intended to be single, let him look at this vile and ugly parody on a beautiful original.

‡ The real *I. tenuifolia*, of Pallas, is something quite different.

§ *Orientalis* is by many regarded as identical with Fischer's *hematophylla*. It is obvious, however, from Sweet's description that the latter is quite a different plant from the former. It is much shorter, smaller, and flowers much earlier. I have not yet come across what has satisfied me as Fischer's *hematophylla*, though I am anxious to do so. The feature which led Fischer to give it the name he did—the red colour of the young leaves and shoots—cannot be relied on for diagnostic purposes; very many forms have the young leaves and first shoots more or less red.

¶ Curiously enough, *longipetala* has an imperfectly developed rudimentary, but still very distinct, crest on the falls; it seems to be a link between the beardless and the crested divisions.

spectabilis. It was gathered by his son, Albert Regel, in Central Asia, and, to judge by its name, ought to be handsome. My plants of it have not yet flowered, and I can say nothing more about it, but Regel promises an early description of it.

As the centre of another group we may take the common American *I. virginica*. This is a vigorous floriferous plant, spreading very rapidly when grown in a somewhat moist rich soil. The flowers vary very considerably in tint, and some of the more deeply-coloured forms are not unhandsome. There is, however, a certain stiffness and formality about the blooms which, to my mind, prevents it being considered as a really attractive kind. More highly coloured, frequently very striking from the juxtaposition of a pure white and a deep rose tint, is the very closely allied *I. versicolor*; but this, too, lacks a certain elegance, so that one is, in looking at it, led to wonder why a flower so beautifully coloured gives one so little pleasure. Many seedlings, both of *virginica* and *versicolor*, are in cultivation; and, though what may be perhaps considered as the typical forms of each are very distinct, almost every intermediate stage between the two may be seen.

One feature of the *virginica* group is the small development of the standards, and we thus pass to the very handsome *I. tridentata* (No. 1 in the plate). This, which is also a North American form, can hardly be said to possess any standards at all; they are reduced to insignificant little peaks, which have to be looked for to be seen. In return the falls are largely developed, highly coloured, and manifest real beauty in their form and markings. It is an abundant bloomer, a strong grower, spreading very rapidly, and in every way a desirable plant. *I. tridentata* is an American form, occurring in the Northern States;* but there is found in Asia a closely allied, or at least a strictly analogous form, *I. setosa*, No. 3 in the plate, which, however, is a far less beautiful plant than its American ally. No one who compares *tridentata* with *virginica* can doubt that the two are closely allied, and yet *tridentata* has quite other affinities. In spite of its comparatively broad leaves, many of its features point to the narrow-leaved *sibirica* group, especially to *orientalis*. On the other hand, it is, I think, impossible to overlook its affinities with the *Kämpferi* group; and its beauty seems to be due to the fact that some of the characters of these two groups are added to those of the plainer *virginica*.

Resembling *tridentata* and *setosa* in one feature, viz., in the smallness of its standards, but in reality quite widely separated from them, is the common yellow Flag, *I. Pseudacorus*, a variety of which is seen in No. 7 of the plate. Common as is *Pseudacorus*, everyone who has grown it fairly, will, I think, be ready to admit its beauty. Whoever has in his garden a pond or a ditch, or even a thoroughly damp spot, ought to plant this Iris largely. Few things, indeed, are more beautiful than a great clump of this yellow Flag, with the tall leaves starting up from the side of a pool, and the golden clusters of flowers gleaming bright in a midsummer sun. Three things it loves—a rich soil, plenty of water, and abundance of sunlight. It is cruel to place it, as I have seen it placed, in some dank dark hole, where the sun's beams never reach it; it is disappointing to plant it, as I have seen it planted, in a dry and stony spot, where summer is to it one long continued thirst. But put it where its roots can run at will in rich black mud, and yet its head raise itself to the full light of a summer sky, and it will be a golden glory throughout the long days of June.

Such are some of the more conspicuous and common beard-

* In the Southern States there grows another form, which in Baker's list is called *tripetala*, and which, from Sweet's description, seems to be a delightful plant. It is more delicate than *tridentata*; its leaves are narrow and linear, not as in *tridentata*, somewhat broad and ensiform. It is found in Florida, and, as far as I know, is not in cultivation in England at the present time. Its re-introduction is a desideratum.

less Irises, but I have far from exhausted the list. I have said nothing of the wide-spread *Iris foetidissima*, worth growing, not for its flowers, which are almost absolutely ugly, but for the bright orange berries of its gaping winter fruit, and still more for its glossy dark green leaves. I have said nothing of the bulbous Irises, which are all beardless forms, and which, save for fear of the anger of the botanists, I would say seem to me even more closely allied to various non-bulbous forms than they are to each other. But I should weary the reader if I said more. Interesting, too, as is the story of their geographical distribution, I must pass that over, and end by saying a few words about their culture.

In nearly all the forms, the one golden rule is that inculcating "wholesome neglect." Let them alone as long as they are doing well, and, above all, do not dig and scratch about their roots. Almost without exception all of them hate to be disturbed, and resent interference by refusing to flower. All of them like the sun. If you care for Irises do not plant them, as they are often planted, right in shade of trees or big shrubs, though some of them, more especially *foetidissima*, will do fairly well there. If you feel that that you are bound to obey the injunctions of the *vide mecum* of gardening by which you swear, and which tells you that Irises are the things for "woodland walks" and "shrubby borders," choose some open glade into which the sun can pour, and not the dark recesses of some leafy cavern. To put the best and handsomest forms, however, in any other position than in the warmest and sunniest spots of the open border is, to my mind, downright wickedness.

They all of them like rich soil, full of decomposed vegetable matter. The coarser and stronger forms will feed on even rank manure, but to the more delicate ones this is almost poison; and all of them, indeed, thrive all the better if their food is given to them in a well-digested form. If it is thus well digested they can hardly have too much of it.

As regards moisture, they vary a good deal. I have already insisted on the necessity of water for *Pseudacorus*, and many of the spuria group thrive best in the damp. Others again, as Monnieri, hate the damp, at least, in winter, and will stand very considerable drought in summer. The conditions which would suit the majority would, I think, be comparative dryness in winter and an abundant supply of water in summer. Unfortunately, this is the very reverse of what they generally meet with.

They also vary a good deal as to the nature of the soil they like best. Some, such as the spuria group and the longipetala group, like a deep, somewhat stiff, but rich loam, and their long, thong-like roots reach down for an amazing distance. The sibirica group, as also the virginica group and tridentata, have finer, fibrous, matted roots, and are partial to a lighter, looser soil, which, however, must be proportionately richer in vegetable matter. Hence many of these are grateful for the gift of peat.

Let me end by speaking of one great drawback to these beardless Irises. By far the greater part of them die down completely in winter; and wise are they to do so. Who in the November weather, which has come upon us, does not envy them? Who would not gladly now go into winter quarters, if he could be sure that he would awake strengthened and refreshed as soon as the bitter half of May were over? But their brown withered leaves makes them in the late fall and early winter an eyesore to those who like to have a garden, but who do not love flowers. I mean the people who insist on having a good "blaze of colour," and do not care how the colour is obtained; who, but for the fashion of the thing, would, if they dare speak the truth, be found to be equally content whether the colours were made up of

delicately-wrought flowers and leaves, or machine-made "dummies" of rag and paper. Such people are generally governed by a demon called "tidiness," who arms them with instruments of mischief called "shears" and "rakes," and sends them, when the winter days come on, into the border to "tidy it up." Such people ruthlessly cut down the ripening foliage, just when the loss of the green summer tint shows that the goodness of the leaf is passing into the root; they tear away the dead leaves, and rob the plant of that wrapping with which Nature strives to shelter next year's shoots and buds from the winter blasts; they scarify and scratch the soil, lacerating the tender fibres, of which the plant stands so much in need; they make the surface smooth, carefully removing every scrap of loose nourishment that is lying about, and leave the ground so that the early winter rains may flatten it into an almost polished surface well-nigh proof against all mellowing influences; and having wrought all this wreek, call it order. Whoever wishes to cultivate Irises, or, indeed, any other flowers for the sake of the flowers themselves, must early recognise that Nature is untidy—that dead leaves and a rough soil are the winter forerunners of the summer's bright foliage and abundant bloom. Whoever is unwilling to leave the foliage of the past summer untouched, so that when it has served its purpose the worms may carry it below to enrich and lighten the soil; whoever is unwilling to let his border soil remain rough and open, so that the rain may pass through it, and the gases of the atmosphere be absorbed by it, and the crumbling hand of frost loosen it; whoever is not ready, when occasions demand, to see his border covered all the winter with "untidy" mulching of rich but inelegant "muck," should not take up the culture of Irises. They, like other plants, are meek and unresenting; they will strive to bloom in spite of all his bad treatment; but he will never enjoy the profuse beauty which is the reward of proper treatment. F.

[For the specimens from which our plate was prepared we are indebted to Messrs. Barr & Sugden, who possess one of the most complete collections of Irises known.]

THE FRUIT GARDEN.

STUDDING WALLS.

WHILST the miserable untidy fashion of training fruit trees by means of nails and shreds is properly dying out, it is remarkable that the simplest and most obvious substitute, viz., cast iron studs, is not almost universally employed in place thereof, as these may be put in entirely at the free control of the cultivator, and need not be withdrawn again under any circumstances. Studs have eyes that admit of stout string being passed through them, or any other material strong enough to tie large branches into their places; they may be driven in all over the wall whilst it is new, and these drying in with the mortar or concrete, as the case may be, will become firmer than when driven in later on. Still there is the undoubted advantage that in close trained trees, such as Morello Cherries, Peaches, Nectarines, &c., where it is the rule to lay in a quantity of wood during the summer, these studs may be driven in where wanted, and once in, as has been stated, may remain permanently. Studs projecting only a moderate distance from the face of the wall do not necessitate that the branches of the trees should stand out from the wall, as is the case when wire is employed, leaving a space through which a cold current of air can pass. The value of training trees on walls is to secure the greatest possible amount of heat both from the direct rays of the sun and from radiation, the heated body of brickwork giving off a considerable amount of heat long after the sun has set. It is therefore obvious that the closer the trees are to the wall the greater must be the heat thus obtained; and no doubt many of the evils that come to trees trained on wires, that stand out 1 in. or even more from the face of the wall, arise from this simple fact, that by this mode of training the chief benefit to be derived from the wall is not given to them.

It is worthy of notice also that in driving in these studs they should be fixed sideways to the branches and not crosswise, as by that mode

of fixing the wood can be tied close to the wall and the stud; whilst if driven the other way, the wood, and especially the young wood that needs ripening, is usually tied across the stud. For large branches soft rope yarn or stout string is always available, and for small branches or shoots stout bast or raffia should be used. For fan-shaped trees the studs should be fixed in that form—thinly near the base, and thickly farther from it; whilst for horizontally-trained trees such as Pears, the obvious course would be to fix them in every alternate course of bricks. This plan has all the advantages of the old nail and shred system, and none of its defects; neither has it any of the defects incidental to the wiring plan. A. D.

FRUIT TREES IN POTS.

IN October last, Mr. Hawkins, Ewenny Priory, Bridgend, Glamorgan-shire, sent us some photographs of his fruit trees in pots, of which the

Coe's Golden Drop Plum.

Prince of Wales Peach.

three annexed illustrations are reproductions; and along with them the following account of the results of his mode of culture:—"Wall fruit, this summer, has proved to be a complete failure in this part of South Wales. I think it my duty, therefore, to strongly recommend orchard houses and pot trees. We have now had nearly three years of failure out-of-doors with the wall fruits, and they have not paid for the labour bestowed on them. Owing to our situation being low, we get dreadful fogs and white frosts. My idea is that walls would pay better furnished with Plums and Pears. I have two orchard houses filled with trees in pots, and trees on the back wall in my lean-to house, which is slightly heated; but my span-roofed one is a cool house. In both houses I always get a good crop. The trees have only 3 ft. of ground each on which to stand, and yet the Peach and Nectarine trees this year in both houses averaged five dozen fruit each, large and small. On Plums and Cherries there were a great many more. Half-a-hundred trees can be grown in a medium-sized house. As the fruit from one tree is gathered, I place it out-of-doors and give the others a little more room. I have a Plum tree in a 15-in. pot which ripened 154 fine fruit. I have Pitmaston Duchess

Pears weighing $1\frac{1}{2}$ lb. each. Three Cherry trees carried 76 dozen. Pot trees in orchard houses are very profitable, and when in bloom they are a grand sight. The Peach called Prince of Wales has borne 89 very fine fruit, and is now in a 15-in. pot. The tree is twelve years old. Souvenir du Congrès, though a small tree, bore 20 Pears; it is in a 12-in. pot; Durodean, in a 13-in. pot, 24 Pears. Coe's Golden Drop Plum, in a 13-in. pot, has borne 7 dozen very large fruit. These are not the only ones I have had like this; I have had more than half-a-hundred quite as good."

HOW TO PACK FRUIT.

To assist young beginners who may have had but little experience in the packing-room, we may describe the system of packing adopted by Mr. Coleman, of Eastnor Castle gardens, whose practice affords the best guarantee of the value of his precepts. By adopting similar

means it is more than probable that better prices would be obtained from the fruiterers, who, to say the least, are dependent upon gentlemen's gardeners for a large portion of the best fruit that finds its way to the tables of the "upper ten." In the selection of fruit for this purpose, Mr. Coleman rightly says there are several points that should be borne in mind: one of the most important being the state of ripeness. It is a common error to allow fruit, particularly Peaches, to ripen on the trees before they are gathered, but the season for this valuable fruit having passed by, these may be passed over for the present. Another great mistake, and one that leads to much damage in transit, is the fear of packing too tightly: indeed, the great secret of success rests here. The most tender fruits—be they Grapes, Peaches, or Figs—must never stir in their elastic packing until removed from the box. Another point is, the best time to send. Unless specially ordered, fruit should never be sent later in the week than Friday morning, otherwise there is danger of losing the market; neither should it be entrusted to the delivery companies, as many boxes of fine Peaches and Grapes are injured after they leave the railway terminus. The best and most profitable plan

is to establish business relations with a salesman who feels that it is worth his while to keep the consignor's name on his books, and to be able to depend upon him for some speciality in time of need. Having done this, the salesman should always have notice the day before that a consignment will arrive at the terminus, when it can be fetched by one of his own porters. These experienced men await the arrival of the train, pay the carriage—which should never be paid in advance—and trudge away with anything under 50 lb. on their heads. It is essential to keep faith with the fruiterer, and to telegraph if a box misses the usual train, as time with him means money. Choose through trains if possible, and cultivate the goodwill of station-masters and guards—a trustworthy body of men who are well worthy of recognition. By way of illustration Mr. Coleman tells us he has frequently sent prize-winning Grapes suspended on stands over 100 miles in charge of a through guard. No porter would be allowed to approach the cases during the time they were under the guard's care. When more than one box of any particular kind of fruit has to be packed, and there is any difference in the quality, it is advisable to divide it into firsts and seconds, as the best quality sent in by reliable growers is often sent down into the vaults for some special purpose, and on no account should damaged or imperfect samples be included.

At the present time Grapes are the leading kind of fruit on sale, and these according to the variety require different treatment. For Black Hamburgs and other kinds of similar contour of bunch many large growers use flat baskets that will hold from 18 lb. to 24 lb. each, and four of these, when packed in a case of suitable size with handles at each end, make up a weight that protects them being turned over by the railway porters. For private growers, boxes of uniform size, that will hold from 18 lb. to 20 lb. each, are best. These should be made of $\frac{1}{2}$ -in. deal, 24 in. long, 14 in. wide, and 6 in. deep, inside measure; the lids should be in one piece, and they should be secured with one small nail or screw at each end. The best material for general packing is dry soft Moss, and as this can be obtained on every employer's estate, a large supply should be secured when the weather is fine, thoroughly dried, beaten with sticks, and pulled to pieces with the hands to destroy the harshness and to free it from dust. Having a supply of boxes and Moss at hand, proceed by placing a layer of Moss, 1 in. thick, evenly and firmly over the bottom of the box, line the box, sides, ends, and bottom, with a double thickness of cap paper, and a single thickness of white silver paper, allowing nearly half of the sheets to hang over the sides for turning over when the packing is finished. White silver paper is not better adapted for packing than the ordinary cap, but its purity of colour throws up the Grapes and gives the black a fresh dressy appearance when the boxes are opened. Having prepared and weighed the box, carry it to the Vinery, place it in a slanting position by tilting one end to an angle of 45°, commence packing by placing good bunches in each of the lower corners, keeping the shoulders well up to the level of the sides, select a third or wedge-shaped bunch that will fit in tightly between the other two. Proceed in this way until the box is half full, then raise the box from the stage or table to a sharper angle, and press the branches still closer together; finish cutting, reserving three short clumpy bunches for the last row; return to the Grape-room, take the gross weight, deduct the weight of the box, and write the nett weight on a card. Place the box flat upon a table, get a supply of Moss near the right hand and commence wedging the fruit away from the sides of the box by the gradual introduction of small quantities of Moss into the cavity formed by drawing the three thicknesses of paper inwards. Gradually work round two or three times, constantly drawing the paper inwards until the berries begin to show signs of rising out of the box. Secure the card containing the weight with a small tack. Strain a sheet of white paper over the top. Turn up the paper from the outside and secure the lid. Some gardeners place Moss or wadding over the paper, and thus take all the bloom off the shoulders, and receive for first-class Grapes the price of best seconds. Nothing more than a sheet of paper should be placed between the Grapes and the lid: the steady but firm pressure of the elastic Moss keeps every berry in its place, prevents the loss of bloom by friction, and the stalks, which stand upwards, protect from injury in transit.

Muscats, being more tender Grapes, require more care than Hamburgs, and the less they are handled the better, as any undue pressure or movement of the berries causes them to change colour when they are opened and exposed to the air. They must, however, have sufficient packing to prevent the bunches or berries from moving in transit. If the bunches are very large it may be necessary to use wider boxes, but in no case need they be deeper than those recommended for Hamburgs. Having prepared the box by placing from 1 in. to 2 in. of Moss all over the bottom, line the sides and ends with long strips of wadding folded in silver paper; weigh the box and proceed as before, by tilting one end to a sharp angle. Place a

doubled sheet of paper in the lower angle, allowing two-thirds to run along the bottom; cut the first bunch, removing all faulty berries, and lay it lengthwise across the box; turn up the ends of the paper and draw them with both hands over the bunch towards the lower end. Then take a strip of wadding, 4 in. by 12 in., place it against the bunch to form a division, lay in another double sheet, and proceed by laying the next bunch, with the shoulders in the opposite direction; turn up the ends of the paper as before, and draw the second bunch close to the first. Add another strip of wadding, and repeat until the box is full, when, by raising it to a sharper angle, the weight of the fruit, aided by very slight pressure with the fingers, will make room for another bunch. Fill up all vacancies round the sides by forcing Moss between the wood and the lining; fold the upstanding ends of the paper neatly and evenly over the fruit, allowing it to project over the sides, and enclose the record of the weight as before; secure the lid with two small nails and cord

Souvenir du Congrès Pear (see p. 561).

each box singly, or a pair of them together. Wadding must be used with great care, and on no account be put in contact with the Grapes.

Lady Downes, Alicantes, and other kinds having long tapering bunches, may be treated as Muscats, placing them transversely across the box; but it is not necessary to use wadding or any kind of extra packing between the bunches, as they are less susceptible to bruising, indeed, the tighter and closer these kinds are pressed together the better they travel. Lady Downes, unless very fine indeed, do not require a 6-in. box, but it simplifies and expedites the matter if all the boxes are of one uniform size, and the extra depth may be reduced by increasing the thickness of the layers of Moss on the bottom. The bunches of these kinds that lie transversely across the box should not, however, touch the paper, which should be drawn tightly over the top, and retain its position by being nailed down with the lid.

The keystone of success in adopting the foregoing system lies in the liberal use of dry, soft Moss, the best and cheapest material for

general packing, and this should be forced down between the sides of the box and the paper until it begins to form an arch near the lid. In proof of this Mr. Coleman's boxes might be turned upside down without injury to the Grapes, and he is, we learn, in possession of a photograph of a box of Grapes taken in London five months after they were cut from the Vines. This box was sent by ordinary train, and the bloom on every berry is perfect. Cording is preferable to over-much nailing. A stout cord should be passed twice round the box, not too near the ends, and once lengthwise, for protection and the convenience of the porters. Printed labels and cards, "Fruit, with care; this side up," should always be used. Success is made up of trifles, and no experienced man will doubt the wisdom of Mr. Coleman's suggestions. Extra fine bunches intended for special purposes, and of course forwarded to secure special prices, should, in all cases where through trains are available, be suspended on exhibition stands exactly as if they were intended for exhibition; but instead of leaving a clear space between the bunches, they should be placed quite close together, well up to the top of the board, when intervening spaces near the points may be filled up with small but perfect bunches. A careful person must see them safe in the van, and the porter who meets them must be in waiting for the train on its arrival. This is the method adopted by Mr. Coleman, and we are sure that his practice will commend itself to those who have to send fruit to a distance.—*Gardener's Chronicle*.

GARDENING FOR THE WEEK.

Flower Garden.

Plants in Cold Frames.—The general treatment required for these will depend much upon the season, which this year promises to be severe. For the last three or four weeks all our plants have been frozen stiff; so keen indeed was the frost for a week that some were frozen in hand-glasses over a hotbed, with the steam rising from the fermenting manure outside the glasses that were over the plants, and that, too, with a mat thrown over them at night. It will certainly be interesting to ascertain how Carnations and Picotees succeed after such a winter, that has frozen the soil in the pots as hard as stone shortly after the layers were taken off, and before much of them had time to make new roots; indeed, it is a fact that many of them had no roots at all when potted, and few growers had the means, if they had the inclination, to make up hotbeds to assist their formation. Many growers of large experience would not venture to help their plants to start by putting them into a hotbed; but I have proved that a gentle heat from a bed of fermenting material is of the greatest service in promoting root action, when layers are badly furnished with roots. A violent, or even a brisk heat would be mischievous, but just enough to cause the material in which the pots are plunged to feel warm to the hand, quickens the root action, and is the means of causing the plants to become established before winter. I had been potting at intervals, some six weeks before the frost set in, a numerous selection of hardy Primulas, and other rare and choice herbaceous plants, and on examining them now I find that many seem to have suffered rather severely from the effects of the frost. The leaves of the *Primula purpurea* section have been quite killed, but *P. capitata*, which seems to be hardier than most, has not suffered. Surely this last named kind is something more than a form of *P. denticulata* (see GARDEN, p. 535). That *P. purpurea*, *P. denticulata*, and *P. cashmeriana* are all forms of the same species there is no doubt, but *P. capitata* is so distinct in foliage that it must certainly rank as a distinct and very beautiful species of *Primula*. The outer leaves of nearly all the *Auriculas* and *Polyanthuses* are killed; but the centres are quite unharmed.

Dahlias.—I had some hope that these were after all well ripened, and that the tubers would winter well, but on examining them last week it is found that they have shrunk up very considerably. I had them immediately placed in boxes, with the tubers just covered with some rather dry sandy loam, and they were then placed in a Vinery in which the atmosphere is kept rather dry, in order to preserve the Grapes that are hanging in it. Those who exhibit Dahlias will scarcely need to be reminded that there is a chance now to overhaul all the boxes, stands, tubes, and blocks, to see that none of them are lost or broken, letting all such be replaced, and the stands should also be painted light green and varnished. When done with, store them where they can be found at a moment's notice. I have previously described the best form of sticks, and have only now to say that they should be washed clean, and be tied firmly up in bundles and put in a dry place.

Phloxes in Pots.—These have been found so useful for decorative purposes that I shall place a number of them in a house from which frost is excluded. My object is to get the plants to start early,

in order not only to produce flowers earlier than they would do out-of-doors, but also to obtain cuttings by the end of February or early in March, so that these also may flower earlier the following season. When carefully attended to these cuttings produce strong plants, which yield good spikes of flowers in 5-in. pots.

Tulips.—These had just been planted when the frost set in, and it is certain that they must have been frozen in the ground ever since. The numerous varieties of named Tulips, as a rule, stand frost well, and they do not suffer from wet, unless it is stagnant water or excessive rainfall; nevertheless, it is questionable if the different species of Tulips are adapted for roughing it, so to speak, in open borders. I have found that *T. Greigi* and *T. stellata* are rather tender, and seem to suffer much during a rainy season like that of 1879. Other plants, however, that succeed well in ordinary seasons were but poorly represented last summer. It will, therefore, be well not to condemn new flowers too hastily, that have only been grown during such a season as the past.—J. DOUGLAS.

Greenhouse.

Epacrises.—Although these are strictly greenhouse plants, and will succeed through the winter in a temperature just above freezing, still, where a good stock exists, it will be found useful to have a portion in bloom early, which may easily be accomplished by keeping some amongst such of the greenhouse plants as require the most warmth, say 45° or 46° at night, with something more than this in the daytime. For this purpose those should be selected that made their growth first and were turned out correspondingly early in the open air, as I have always found that these plants at once set their flowers as soon as put outside in the summer, and by this are influenced in their time of blooming. The large-flowered, upright-habited varieties are the most useful for blooming early, and they are also the best for general use, especially for providing cut flowers, as every shoot of the preceding season's growth may be cut without injuring the plants; in fact, to keep the erect-growing kinds from getting too tall and thin, it is necessary to shorten the whole of the shoots to within some inches of where they were cut back to the year previous. It seems strange that there are not more of these most serviceable plants grown than there are, so easy are they to manage, and not subject to get into a bad condition in the way that many of the more tender hard-wooded plants are; added to which their leaves are so stout as to almost defy the attacks of the generality of insects, another important consideration.

Large-flowered and Fancy Pelargoniums.—Those plants of the large-flowered section that were shaken out the latest after being cut back and treated in the usual way, should by this time have made sufficient new roots to permit of their being moved into their blooming pots, which should be about 8 in. in diameter. All Pelargoniums are better hard-potted, but for this section particularly the soil should be made very solid; it should also be in a medium condition as to moisture, and little water should be given until the roots have had time to fully establish themselves. There is no description of soft-wooded plant which makes any growth through the winter that from this time to the end of February requires to be kept with the soil so dry as these and the fancy varieties, without which they never can be grown satisfactorily. They should have all the light possible, and be kept at a temperature of about 40° at night, with a little air every mild day, but not exposed to keen winds. The dwarf-growing, free, early-flowering, decorative kinds so largely cultivated by market growers, and which are the most useful by far for general purposes, as they will bear enough heat through the winter to have them in bloom by the beginning of March, should be kept now at a temperature of 45° or 46° at night, with sufficient warmth in the daytime to permit of a free admission of air which prevents their becoming drawn. As soon as the flowers show freely, which they ought to do by this time, the plants will bear a little liquid manure once a fortnight or so, but they must not have it over strong, or it will cause them to run too much to leaf. They ought to be kept close to the glass in the lightest house available, and especial care should be taken to see that they are free from aphides, on the first appearance of which they ought to be fumigated.

Chrysanthemums this year have suffered through the sunless season quite as much as most other things, and their flowering has not generally been nearly equal to that which is usual; this has been especially the case where the propagation was put off until spring, the result of which always is that the plants never get their wood so well matured before autumn preparatory to flowering, as when they are propagated earlier, and another consequence arising from spring propagation is, that when the plants are struck thus late, it necessitates their being kept warmer during the process of rooting than they should be, during which time they make soft top growth, and the leaves so produced are so deficient in texture that no amount of after attention can keep them from decaying before the plants get

no flower. It is well to remember that the Chrysanthemum is a hardy plant, which neither requires, nor never should be subjected to much artificial heat. If cuttings such as are produced from the base of the plants, choosing those that are stout and not drawn up weak, are at once inserted half-a-dozen together in 3-in. pots, placed in a light position in a cool house, kept moist, and covered with a bell-glass, they will root without getting at all drawn. My practice has been to get some large common slates, lay on these an inch of sand, keeping it moist, and on this place the pots close to the front or end lights of a cool greenhouse or pit, giving a little air at times, but not so much as to cause the cuttings to flag. As soon as they are rooted, pot off singly, and inure them to the air of the house, from whence they may be moved to a cold pit or frame, just keeping them through the winter out of the reach of frost. Those who will give this method a fair trial will find that it is better than leaving the propagation until spring, when there is always enough work that cannot be got on with previously. By the system which some growers adopt of dividing the old plants, and growing these a second year, very large examples may be obtained, but they are not nearly so useful or nice looking as those from cuttings struck annually. If there is any trace of aphides about the cuttings before they are put in I should advise their being dipped in Tobacco-water, which should be allowed to remain on them for a short time, and then be washed off, previous to inserting them in the pots, as I have found that they, in common with most other plants, do not root freely if it is allowed to dry on them. A selection of varieties for general decoration, made, as is often done by the inexperienced, from the stands of cut flowers seen at the exhibitions, is much like that of Roses chosen under similar conditions, and is calculated to do anything but turn out to the satisfaction of the grower, as the individual flowers, though fine, are the produce of varieties that naturally are not able to mature a sufficient number of blooms to make them most useful for ordinary purposes. The kinds that bear medium-sized flowers are the most suitable for general pot culture. Of late years few of the varieties find favour, except the globular-formed flowers with incurved petals, though many of the old more open shape are preferable, of which the bluish-tipped *Hermine*, and the old pale yellow *Annie Salter*, may be taken as examples. The medium-sized white *Mrs. George Rundle*, with its Primrose-coloured and deep yellow sports, *George Glenny*, and *Mrs. Dixon*, should be grown by everyone, as they stand unequalled in their respective colours, and are remarkably free flowerers. The velvety crimson of *Julie Lagravère* is another of the very best, and the different coloured varieties of the larger-bloomed *Pompones* are also amongst the best to grow in pots, either when the plants are wanted for decoration, or the flowers for cutting. Large perfectly formed flowers, in accordance with the florist's standard, are desirable in their way, but profusion of bloom, with less formality, will always be prized by most people; for this reason, the irregular flowered Japanese kinds should be grown in considerable quantities, being much more elegant, especially for cutting; amongst the most desirable of these are the *Daimio*, pink and rose; *Triomphe d'Hyeres*, orange-red and yellow; *Red Dragon*, chestnut, tipped with yellow; *Gloire de Toulonse*, crimson, sometimes beautifully mottled with white; *Elaine*, white and carmine; *Bijou of Guernsey*, yellow; *Fair Maid of Guernsey*, white; *Madame Lemoine*, primrose and lilac; *Dr. Masters*, red, tipped with yellow; *Harlequin*, crimson with gold stripes; *Soleil Levant*, clear yellow; *Sanspariel*, red; *Robert Fortune*, amber; *Marginatum*, lilac and white; *M. Astier*, red, tipped with violet; *Album striatum*, white, with violet stripe; *Abd-El-Kader*, crimson; and *Jane Salter*, white, striped with lilac.

Succulent and Kindred Plants.—The quaint forms which many of these possess have, of late years, since singular-habited, fine-leaved plants have come more into general cultivation, commended them to many. Numbers of the smaller-growing kinds, seldom met with, are well adapted for greenhouse and conservatory decoration in houses where the largest species of *Agaves*, when these have attained anything like their full size, could not be found room for. They are easily grown, the principal essential being that the pots are thoroughly drained in the first instance, and care always afterwards taken that the drainage does not get foul through the presence of worms, which, like other things they are subject to, and going, as many of them do, for a long time without requiring repotting, these are the more liable to cause the drainage to become clogged up, in which case the succulent roots are apt to rot, and although from the tenacity of life possessed by many of the species this may not kill them, yet it generally results in an unhealthy condition and loss of leaf. Amongst the handsomest are the different forms of *Agave filifera*, *A. Verschaffelti*, *A. Schidigera*, *A. picta*, *A. lophantha*, *A. dealbata*, and others of like habit. With most of these it may be observed that it is well to keep them somewhat warmer through the winter than a cool greenhouse; but they will be quite at home in conservatories, where, as is usual, a little more warmth is maintained. Moderate-sized examples of the different forms of *A. americana*,

both green and variegated, are equally effective used in like manner, and they will bear anything short of absolute frost. These last-named plants are extremely useful for placing in halls, verandahs, or anywhere in proximity to a dwelling-house, as well as in more distant parts of a garden during the summer-time, where their quaint, distinct habit of growth, with their elegantly-curved leaves, adapt them for associating well with other things. *Agaves* are readily increased from the suckers which plants, after they attain a moderate size, generally produce freely. I have usually taken these off any time during the winter, potting them singly in moderately dry soil, and giving no more water than will keep the soil slightly moist until the roots begin to move. *Yuccas* also might with advantage be much more generally employed in greenhouses and conservatories than they are, as, beyond the ordinary variegated *Aloe*-leaved variety, they are not much met with; *Y. albo-spica*, *Y. filamentosa*, *Y. concava*, *Y. glauca*, and *Y. filifera*, are all plants deserving of cultivation where singularity of form is appreciated. The smaller-growing greenhouse *Dracanas*, such as *D. congesta*, *D. lineata*, and *D. rubra*, if grown in quantities, are amongst the best subjects for general decorative purposes that can be cultivated, as it is not alone in greenhouses and conservatories where they are of use; they are equally so for the embellishment of dwellings in the numerous ways in which plants are now employed. Respecting the last-named kind, *D. rubra*, it appears to be comparatively little known beyond the London nursery and market growers; it may be described as having somewhat the appearance of *D. indivisa*, very much reduced in size, both as to the length and breadth of the leaves. It is really handsome, and keeps in good condition much longer in places not well suited for plants, continuing in a healthy state. Any one commencing the growth of these plants cannot do better than get in a stock during the dormant season, when there is usually more time to attend to such matters than in the spring and summer.—T. BARNES.

Indoor Fruit.

Pines.—In Pine pits furnished with hot-water pipes for the production of bottom-heat, the plants require more water than where the heat is produced by leaves or tan. In the latter case very little water indeed is required, but the plants that are grown under the first named conditions will require extra attention in that way during severe weather, when hard firing is a necessity; for if once they get really dry, one of two evils is sure to ensue, viz., premature fruiting, or else, in the case of more advanced plants, improperly developed fruit. A selection should now be made of the finest plants of *Queens* that have had the longest rest; these should be placed in a compartment by themselves in a bottom-heat of 90°, and in a top heat of from 65° to 70°, and they should have a liberal watering with tepid water, which will soon induce them to show fruit that will ripen from May onwards. In many respects this is the most valuable batch of fruiters of the whole year, particularly in the case of those who have to study to get supplies for the London season. Succession plants should still be kept on the resting side of dryness, and if they are becoming crowded, and likely to get drawn from being so close together, spread them out in the room that may be made by throwing away the old fruiting stools, after denuding them of suckers. Plants that are swelling off fruit should have frequent supplies of tepid manure water till the fruit changes colour, when it may be discontinued.

Vines.—Late Vines, being quite clear of foliage, there will be little now to engender a damp atmosphere, particularly if internal borders are, as they should be, covered with mats or dry straw; so that if the fruit has been well ripened, it would keep in plump condition on the Vines for at least three months; but this is undesirable, taking into account the future well-being of the Vines; provision should therefore be made for keeping the bunches in bottles of water, and all should be cut about the second week in January. We have never experienced any difficulty in keeping Grapes in good condition till June, except once, when they were left on the Vines until the middle of February. In that case, when placed in water, the sap having become active by the mild winter of that year, the berries cracked, and, as a matter of course, decayed, so that under no circumstances should harvesting of the fruit be deferred beyond the second week in the New Year; Vines should then be at once pruned and otherwise afforded the proper conditions of rest. Proceed slowly with the forcing of early houses, preferring rather to make up lost time after the Grapes are set than to risk the production of tendrillike "shows" by hard forcing. Pot Vines, if placed, as they often are, close to hot-water pipes, will need a large amount of water. When practicable, it is always best to plunge the pots in a bed of leaves, both to save watering and afford a slight bottom-heat.

Peaches and Nectarines.—Pruning, tying, cleaning of houses, &c., should all be now completed, and the first house may have an advance in temperature, say 50° as a minimum at night, and from 5° to 10° higher during the day, to be increased in mild

weather when ventilation can be given. See that inside borders are well moistened through, and kept so by the application of tepid water whenever necessary. A thick mulching of litter or Oak leaves not only keeps the borders in an equable state, both as to moisture and warmth, but gives off ammonia, which, till the trees come into flower, is beneficial, and prevents the necessity of constant syringing to maintain the proper amount of moisture.

Figs.—As soon as the pot trees that are to yield the first supply of fruit have begun to expand their terminal buds, increase the temperature and air-moisture, and, let the trees have an abundant supply of warm manure water, and in the absence of litter or leaves to give off the desirable ammoniacal vapour, the floors and walls may also be occasionally syringed with the same. Keep the glass clean, and the trees as close to it as circumstances will permit. The earliest planted-out trees may now also be started by the turning on of sufficient heat to maintain a night temperature of 45°. Syringe the trees in dry and mild weather, but the floors and walls only in frosty or damp weather. Complete the pruning, tying, dressing, and cleansing of houses, and top-dressing of borders at the earliest period, and to effectually rest the trees keep them well supplied with air till the time arrives for starting them.

Strawberries.—The plants that are being started on shelves in Vineries, Peach houses, &c., ought to be regularly syringed till they come into bloom, as a preventive against red spider. It is on this account—liability to attacks of spider—that we prefer to start them in a frame filled with leaves, as recommended in THE GARDEN (p. 512), for though plenty of both top and root moisture will keep away spider, some plants are almost sure to escape notice and get dry, and then its advent is a certainty. When first placing them in forcing quarters examine them to see that the drainage is clear and the balls free from worms. Rub off any mossy vegetation that may have formed on the surface, but on no account break up the surface soil, for to do this is simply to destroy many of the best roots. Those plants that from want of frame room must perforce remain in open quarters should at least have sufficient protection to prevent the pots being smashed by the action of frost, and felt, boards, or tarpaulin should be used to throw off rain and snow.—W. W.

Kitchen Garden.

The severity of the weather during the last two or three weeks has proved most disastrous to the late Cauliflower and early Broccoli crops, for, even in spite of protection, there is but a small per-centage left. Such a fatality can only be accounted for on the ground of immature growth, consequent on the excessively wet and sunless weather, as was the case this season. The only green crops that have survived without injury are Brussels Sprouts, Kales, and Savoys; these, therefore, should in future be planted in larger quantities than hitherto. Now that the frost has disappeared, it will be necessary to go over plots of Greens and remove all decaying leaves. Such vegetable refuse makes a valuable manure when it can be dug in whilst in a green state, but if this cannot be done it should be thrown together and intermixed with a little fresh lime, which will add to its value as a manure. The fact that vegetable crops have suffered so much suggests the propriety of at once taking steps to force additional quantities of Seakale, Asparagus, French Beans, and Carrots, and also of sowing at once in boxes, in heat, Cauliflowers, Brussels Sprouts, and Coleworts; the first-named will keep up a succession to those that were sown in autumn and are being wintered in frames. Brussels Sprouts cannot have too long a season to get them tall and productive, whilst Coleworts are always acceptable, and no green crop can be had so quickly. This crop is the more important, as autumn-planted Cabbages seem to have suffered almost as much as the Broccoli. Potatoes should be carefully examined; all the early seed tubers should be laid in single file to sprout, on floors or shelves, free from frost. Some of the first earlies may now be put in shallow boxes of leaf soil, and placed in frames to start them; and, as soon as fairly rooted into the mould, they should be finally planted in forcing pits or pots; we find the latter a very convenient mode of growing the earliest batch, as they can be moved from place to place as circumstances demand. Myatt's Ashleaf Kidney and Fenn's Early Market Round are both excellent varieties for pot culture. If not yet done, Asparagus plantations should have a thick covering of well-rotted manure, but no alleys should be scooped out to cover it; such a proceeding is not only useless but hurtful. New plantations of Horseradish and Rhubarb may now be made at any time, and established plots should be manured and dug over. Still keep Globe Artichokes well protected, though, if time can be afforded, the protecting material should be removed when there is no likelihood of frost, and again applied on the first indications of it. Let all vacant plots of ground be manured, and dug, trenched, or ridged up as soon as possible, in order that they may have the fullest exposure to the ameliorating influences of the weather. A plan of cropping for the forthcoming season should at once be decided on, and in making it

out see that the various plots have the crops varied as much as possible from those of last year. Taking the same crop twice consecutively from the same ground not only impoverishes it more than it otherwise would be, but the produce is less, the only exception being when the ground is deeply trenched.—W. W.

Extracts from my Diary.—December 22 to 27.

FLOWERS.—Moving *Eucharis amazonica* and a few more *Bouvardias* into the greenhouse. Picking decayed leaves and flowers off *Primulas*. Staking out fronds of *Adiantum Farleyense*; also placing stakes to *Poinsettias* and *Euphorbia jacquiniæflora*. Getting out a few more Roman Hyacinths, and placing them in heat; also a few more *Roses* and *Dielytra spectabilis*; throwing out linings of pits, and turning manure and leaves ready for replacing them. Getting a few more *Azaleas*, *Deutzias*, and *Lily* of the Valley into gentle heat. Erecting stage in late Vinery for bedding plants.

FRUIT.—Fixing shelves in fruit-room for the reception of Grapes in bottles. Pruning *Trebbiano* Vines, and selecting well-developed eyes for purposes of propagation. Tying third Peach house. Pruning Gooseberries and Currants on north walls. Chopping suckers up from Plums and Apples. Cutting down Vines in pots, growing for forcing hereafter, and placing them in a cool Vinery.

VEGETABLES.—Covering up Lettuces with a little hay for protection from frost. Covering up clamps of Potatoes with straw in anticipation of severe frost. Cutting all Seakale and Mushrooms ready for use. Covering up another batch of Seakale on beds outside. Manuring ground ready for digging. Potting next batch of French Beans, and making next Mushroom bed outside. Looking over Asparagus, and getting in next lot. Emptying pit for Rhubarb. Placing succession Lettuces and Endive in Mushroom house to blanch.—R. G., *Burghley*.

AMERICAN NOTES

The Adornment of Cemeteries.—One of the most beautiful sentiments offered at the shrine of departed relatives and friends is that which keeps beautiful with leaves and flowers the quiet abodes of the dead. It would be well, however, if more taste and knowledge of the habits of plants went with the active devotion of this character often evinced. If the fence monstrosity could be done away with altogether, our cemeteries would be greatly improved; but if the fence must remain, above all things do not crowd the place with stiff hedges of *Arbor-vita* and other large-growing plants. Let an irregular, graceful fringe, or belt, of dwarf evergreen or deciduous shrubs mask the fence with varying outline and somewhat formal repetition, as befits the dignity and regularity of the place. Inside should grow scarcely anything but greensward, with low growing vines and flowers wandering about with modest freedom. If here and there a shrub is used, it should be of the rarest mould and dwarfiest form—choice bits of arboreal sculpture rather than mere foliage and flowers. The taste exhibited in the ornamentation of burial grounds cannot be too severe, chaste, and refined. Flowers we may have, but they must grow and bloom within limits, and the colours and forms of evergreen and deciduous trees, for both summer and winter landscape, must blend deftly and harmoniously, lest anything *bizarre* mar the peaceful nature of the spot. And, in addition to all this, let me say that in no species of lawn planting does the importance of intelligent pruning, fertilising and watering apply with such force as in that pertaining to God's Acre.

Magnolia Fraseri, the Ear-leaved Umbrella Tree, is found in Virginia and Kentucky, along the Alleghanies and southward, though but sparingly. This blooms in June, bearing yellowish flowers, and sometimes again in autumn. It forms a small tree, and is therefore well adapted to small lawns. The seeds are always scarce.

The Japanese Eulalia.—The tall and lovely Grass, called *Eulalia japonica variegata* in the catalogues, blooms so late that the panicles often have their development arrested by frost, but this time they have shown what they can do if let alone. Our circular clump, 10 ft. or so across, is a dense mass of the pale variegated foliage, and 6 ft. or 8 ft. high, above which the feathery panicles, at first dark purplish and then light grey, wave their spray-like branches in pleasing contrast, making the mass most attractive to passers-by.

Wanted a Word.—It is a pity that there is no word in common use that comprises both agriculture and horticulture. If we speak of the *Rural* as an agricultural or farm journal, we feel we do not do it justice, since it gives as much attention to horticulture as to agriculture, and the constant use of both words is out of the question. It does not seem that the word *terraculture*, though the right

one by derivation, will ever come into general use. To speak of terracultural colleges, stations, and newspapers, would sound funny enough. Horticulture is properly garden culture, but it is now accepted as including fruit culture, and flowers, shrub, and ornamental tree culture also. We want one popular word that shall comprise everything that is meant by both agriculture and horticulture.

Tomato Progress.—We find that several of our readers, accepting our suggestion, are working to produce a variety of Tomato that shall keep better than any at present known in the market. One of our friends in Ohio has a cross between the Acme and Trophy that will keep well for from fifteen to twenty days. We ourselves have been selecting seeds for two or three years with this object solely in view. In another season we hope to be able to report our progress. In breeding for a better-keeping sort, we should never lose sight of productiveness, and that quality, so valuable in the Acme, of ripening about the stem.—*Moore's Rural.*

The Yellow Clematis.—Those who only know the Clematis from the magnificent Japanese and Chinese hybrids, which, with their enormous flowers from 4 in. to 6 in. or more across, may be regarded as among the triumphs of modern horticulture, can hardly be aware of the great variety which the genus presents. Not all the Clematises are climbers, as there are some herbaceous species valued as border plants. Among the climbers, besides the grand hybrids already mentioned, are others so strikingly unlike these, that one would not at first sight take them to belong to the same genus. Some of these we have noticed from time to time, notably the scarlet Clematis (*C. coccinea*); this represents a group the flowers of which do not spread open, but the sepals form a sort of urn-shaped flower. Then there is a group with quite small flowers in large clusters, producing a profusion of bloom; of this group there is none better than the Virgin's Bower or Traveller's Joy. Resembling this in appearance is *C. Flammula*, the Sweet-scented Virgin's Bower, a name it well deserves. In still another group, we find flowers of medium size, and solitary, upon long stems, in the axils of the leaves. To this group belongs *Clematis graveolens*, the flowers of which, something remarkable among these plants, are yellow. The plant is rather slender and delicate, having less robust stems than the other climbers. The foliage, of a fresh and pleasing green, is more finely cut than in the other species, each leaf consisting of three to five sharp-pointed leaflets which are themselves cut or lobed. The flowers are solitary, of only four spreading sepals, and are about 1½ in. across; their colour is a pale Lemon-yellow. This plant, coming from the higher mountains of Chinese Tartary, is a comparatively recent introduction. As may be inferred from its origin, it has proved perfectly hardy in the severe climate of New England, and this, together with its delicate habit, its very free growth, and the unusual colour of its abundant flowers, will make it very popular when it becomes better known. It blooms in late summer, and its flowers are soon succeeded by globular clusters of fruits, the long feathery tails to which are of a very pale green, and about as showy as the flowers. The specific name, *graveolens*, means "heavy-scented," the applicability of which is not readily seen (or rather smelt), as we have not been able to discover a perceptible odour, heavy or otherwise. "Heavy-scented Clematis," sometimes given as a common name, is not a very pleasing one, besides it is quite too long, while "Yellow Clematis" is preferable in several respects, and is more-
over descriptive.

Osbeck's Sumach.—This has pleased me much by its generally robust aspect, and the healthy vigour of its dark, thick leaves. The plant is a native of Japan, and has been called, in some European Continental gardens, *Rhus japonica*. I came across it several years ago at Ellwanger and Barry's. Its leaves resemble those of our native dwarf Sumach (*R. copallina*), in having the common petiole winged between the leaflets, but are much larger, and without the shining surface of the other. Prof. Sargent informs me that it flowered with him this year, and that it is still more attractive in bloom. In autumn it takes on yellow, orange, and scarlet tints, which are blended into every intermediate shade, and all with a brilliancy and richness of colour that, should I use adjectives to adequately describe it, I should seem extravagant, while the printer would use up all his exclamation points and get "out of sorts."—*American Agriculturist.*

Mr. Chapin's Great Orchard.—We have noticed in this journal (*Country Gentleman*) in former years the extensive Apple orchard of Mr. Oliver C. Chapin, of East Bloomfield, in Ontario County, N. Y., covering over 100 acres. The editor of the *Rural Home* has recently paid it a visit, and furnishes some additional particulars. A part containing 50 acres has been seeded three years and pastured by sheep. The exterior of the orchard has borne well this year; the interior but little. The canker worm commenced its roads, and was worst last year on the interior trees. Mr. Chapin

showered them with a mixture of Paris green and water, which brought them dead to the ground in a few hours. The water was drawn in a box holding over 200 gallons, in which was mixed 2½ lb. of Paris green. A forcing pump and hose threw a stream high above each tree, where it broke into spray, and falling sprinkled every part. The whole orchard contains 120 acres. No heavy crops have yet been raised. One year he picked 7000 barrels. There are over 5000 trees. The estimate this year is over 3000 barrels. When the growth of the tree is rapid, he seeds to Clover for a few years, and ploughs it under, which appears to answer well. He cultivated constantly when the trees were young. Most of his orchard is planted with the Baldwin.

The Scuppernong Grape (*Vitis rotundifolia*).—Some years since I abandoned all Grapes except this kind, which I find to be the only one exempt from disease. I have now quite a large quantity of it under cultivation, having raised a large number of seedlings. It is a white or yellowish Grape, with berries varying in size from ¼ in. to 1¼ in. in diameter. None of the varieties I have ever fail to produce good crops, and the Vines are entirely free from disease in Vine, leaf, and fruit. The weight of fruit on each Vine is beyond belief by those who have never seen this class in full bearing. I have this season had arbours crushed down with the great weight of the fruit on them, although they were built of good, stout Chestnut fence rails. Some Grape growers complain that the clusters are too small; this is not so; each Vine is a huge cluster in its entirety.

Tuber formation in *Tropaeolum tuberosum*.

In gathering them when ripe, they are shaken down on to sheet made for the purpose, instead of being picked by hand, as is the case with the cluster varieties; and in 50 bushels of the berries, which are gathered entirely free from stems, one would not find a rotten or imperfect berry. My Vineyard, which is a small one, has this year yielded about 4 gals. of "must" or juice per bushel of fruit. I have one Vine, a seedling from the Scuppernong, raised by myself, which will compare very favourably in quality with the Black Hamburg, while the berries are from 1 in. to 1¼ in. in diameter, of a black colour, speckled with russet. This class of Grapes always bloom about the 15th of June, and consequently the clusters are never injured by frosts. The growth of the fruit is very rapid, the crop being ripe by Sept. 25. Could not this Grape be cultivated in Vineries at the North? It is killed to the ground when the mercury gets to zero. I have one variety that ripens the last of August. It is a fine, large black Grape, also a seedling from the Scuppernong. Vines of this class are never pruned, and rarely manured or cultivated. The roots running an inch or two below the surface of the ground, cultivation is entirely impracticable, and the leaves from the Vines furnish most of the manure they get. Stable manure is death to the Vines, while they delight in lime and decayed vegetable matter. Another peculiarity is that the Vines cannot be propagated from cuttings, as are other varieties, but only from layers, so that it is a slow process to increase them.—*Country Gentleman.*

TUBEROUS-ROOTED TROPEOLUM.
(T. TUBEROSUM.)

THIS species, which is tolerably well known, is a rampant climbing plant, and when planted near the foot of a warm wall, or trained up a fence of brushwood, it forms by no means an inconspicuous object.

It is quite hardy, but a heap of ashes over its tubers affords it congenial protection during winter, and enables it to sprout away with renewed vigour in spring. This *Tropæolum* attracted attention some years ago as being one of a rather long list of plants from time to time recommended as substitutes for the Potato. My present object in alluding to it, however, is to direct more particular attention to its bulb-tubers, or underground stem development, and I am sorry that I have not tubers of other allied species of *Tropæolum* at hand so as to study them by comparison. What I want particularly to point out is the intermediate character of these tubers, and the distinct manner in which indications of scales are shown. From these tubers we gather that both bulbs, as in Lilies, and tubers as in this *Tropæolum* and in the Potato are shortened or compressed stems, the leaves or foliolar organs of which are thickened and consolidated into scales, which, in the true Lilies, are free or ununited, but are, in what are termed tubers, fused together into a solid mass just as the wax model of a Lily bulb might be fused by gentle pressure in the hand if held before a fire. In the case of the Potato the identity of the scales is well-nigh lost, but if the green above ground or axillary stem-tubers of a Potato be examined, their condensed stem-like character becomes more clearly apparent, since the rudiments of leaves are sometimes developed by them, and what we call "eyes" are seen to be the true axillary buds of a short plethoric branch of the main stem. The tubers of this *Tropæolum* are beautiful in themselves, being of a soft yellow tint, prettily and distinctly marked with purple; moreover, they show the narrowness of the line which divides the bulb proper from the tuber so well that a figure of them may be of some permanent interest. I am indebted to Miss C. M. Owen, of Knockmullen, Gorey, Ireland, for the materials from which the engraving has been made, and I should be obliged if anyone will spare me tubers of any other species of this

genus for purposes of study and comparison. The whole question of underground stem and root development is so important, from a cultivator's point of view, that one may be excused for regretting that it is not more generally studied and alluded to in garden literature. As shown in the annexed engraving, the tubers are clustered on the lower part of the stem; each tuber springs

from the axil of a former leaf or its representative, and so each tuber clearly represents a branch of the main stem, which, with its foliolar organs, is shortened, thickened, and fused together so as to represent a tuber.

F. W. B.

Flowering spray of *Tropæolum tuberosum* (reduced)

Does Ivy Injure Buildings.—This question has been many times asked. In my monograph on "The Ivy," I treated it at some length, and with the aid of evidence adduced in an important inquiry as to the effect of Ivy on the fabric of English churches. My friend M. Sisley, of Lyons, informs me of neighbours of his who actually dread to plant Ivy near the walls of their dwellings, from the apprehensions they entertain of consequent damp and injury to the structure. So long as such opinions prevail it cannot be too often repeated that the attachment of Ivy to walls is altogether an advantage. If the walls are damp before the Ivy is planted, the damp will disappear as the Ivy overspreads their surfaces. If the walls are dry to begin with, Ivy will keep them so, by a double action; for should dampness occur through some accident, the Ivy will suck out the moisture into its own substance, and in the event of driving rains, that occasionally act with force on walls, the imbrication of hard leafage will prevent the access of rain to the structure, and thus Ivy is not only a remover, but a preventer of damp. As regards the integrity of the structure, however, the case is less clear. Fissures in walls clothed with Ivy will sooner or later be discovered by

the plant and filled up, and then mischief may be expected. When a shoot or root pushes through a fissure in a wall and is left undisturbed, its natural growth soon begins to tell upon the structure. As the little Nut tree carried the millstone, so the slender shoot of Ivy will by increase of girth begin to push against the sides of a fissure, with the certainty of increasing it, and the probability of bringing the wall down. But where the wall is sound it is exposed to no such

danger. Ivy does not make fissures, however quick it may be to discover them where they already exist. It follows therefore that, as a rule, Ivy may be regarded as defending against time and accident the walls that afford it support.—S. H., in *Gardener's Magazine*.

TREES, SHRUBS, AND WOODLANDS.

VARIETIES OF THE NORWAY MAPLE.

PERHAPS if the mass of persons wise in tree planting had to choose one tree as combining most beauty and hardihood, they would select the Norway Maple. In fact this very selection has been made by a vote of just such authorities. That the Norway Maple in its natural form is excellent in every way desirable for a tree is unquestionable, but at this time I wish to call attention to the corresponding value of its varieties. I wish to note that in no way do they fall short of the excellence of their parent, but that, on the contrary, they even surpass in certain ways their worthy progenitor. The variations of most hardy plants assume one of two or three types. They are either variegated in colour, or cut-leaved or weeping in form. Varieties of Norway Maple never weep, as far as I know, but they do divide and colour their leaves in very curious as well as delightful fashions. Let us look at a few of these varieties:

Acer platanoides cucullatum is the least varied of the cut-leaved forms of the Norway Maple, but its large round leaves are curled down at the edges in a very striking manner. In general growth it closely resembles the ordinary Norway Maple, as indeed do all the varieties I shall name.

A. platanoides laciniatum, popularly called the Eagle Claw Maple, is perhaps the best known of the different forms of Norway Maple. Fine specimens occur here and there throughout the country, although even yet this noteworthy tree receives little attention. The term "Eagle Claw" fairly describes the form of its leaves, which constitute its chief peculiarity. Plated curiously, curled, and somewhat compressed, the leaves are evidently claws. Yet the leaf is not properly *lacinated*, or cut-leaved—hardly enough to secure a moderate amount of actual claw. At some distance, however, the claw-like effect is striking and interesting. Of course, such a tree as the Eagle Claw Maple, though decidedly marked in form, needs the position of a single specimen, that it may worthily exhibit its charms without being lost in a mass of somewhat similar foliage. This arrangement, indeed, suits all the peculiar forms of Norway Maple. Otherwise, if it be desirable to associate them with a group of the parent species, they should be planted a little without the mass, each one distinctly by itself.

A. Lobergii exhibits the most extreme type of the cut-leaved form of Norway Maple. The leaf is literally divided into several parts down to the very leaf stem itself. Indeed, one might readily mistake these sub-divisions for actual leaves, instead of parts of one leaf as large as that of the ordinary Norway Maple.

A. Schwedleerii, the most charming variety of all, adds to beauty and breadth of outline the attraction of vivid colour. And what colour! It appears on the leaf in early spring, and flushes the young growth with red until late in June. In August, again, and September, there is a glow of red and purple amid the pervading dark green tints. The contrast thus made is remarkably striking and agreeable. It would add doubtless to the charm of *Acer Schwedleerii* if it continued green throughout July, but it is well known that the variegations of leaves can seldom resist the subduing effects of mid-summer suns. The purple Beech does no better at that season than *Acer Schwedleerii*, and to class the latter kind with the purple Beech for rich and permanent colouring is certainly high praise. Perhaps my expressions of admiration may seem a little overwrought, but I believe all who have looked at the right season on *A. Schwedleerii* will bear witness to the truth of my assertions. It is, in fact, an excellent tree in every way—as excellent as its parent and far more lovely; not that the attractions of its parent on the lawn are not of the highest order.

As a street tree, the Norway Maple is perhaps too round-headed—too heavy in the quality of its shade. This peculiarity would, of course, apply to all its varieties. Nevertheless, general experience has fully proved both species and varieties to be good and attractive ornamental trees under all circumstances. The smoke and dust of the city, and the winds of the plain and sea, alike fail to overcome their rugged endurance. Everywhere, in fact, the Norway Maple; and all its varieties transplant well, and endure persistently the most trying ordeals a tree can be expected to endure and live. In growth, the Norway Maple and its varieties establish that healthy medium which indicates enduring strength and beauty, combined with active vigour.—*Country Gentleman*.

NOTES & QUESTIONS ON TREES, SHRUBS, & WOODLANDS.

Hydrangea rosalba.—I cannot refrain from speaking briefly of a *Hydrangea* accidentally met with during a recent visit to the Central Park. While wandering about a wild rock garden on a hillside in the upper part of the park, near Mt. St. Vincent, a friend pointed out a mass of large, resplendent corymbs of rosy-crimson flowers which were borne by a plant of strangely unfamiliar appearance, and yet one that we felt we ought to know. Soon afterwards, however the name dawned on the mind of my friend, and we both recognised an old acquaintance seldom seen in flower, viz., *Hydrangea rosalba*. We attributed the existence of the flowers in this case to the very sheltered, dry position the plant occupied. Thus favoured, the wood had fully ripened, and consequently passed through a severe winter unscathed. The bloom also had developed with peculiar excellence under the favouring peculiarities of the place. Few in this climate ever see the flowers of *Hydrangea rosalba* at all, blighted as it is by ordinary winters.

Magnolia Thurberi.—I fear a hardy Japanese *Magnolia* that has been termed *M. Thurberi*, must give up this cognomen for that of *M. Kobus*. It bloomed this year for the first time with us, and the peculiarities both of the appearance of its flower and time of flowering, agree very closely with the description given of *M. Kobus* by M. Maximowicz and others.

Acer polymorphum.—Query: Shall we term the many-formed Japanese Maples *polymorphum* or *palmatum*? There are authorities for both specific names, and they are used interchangeably. I believe they should all be termed *polymorphum* or all *palmatum*, and that the question is only to be settled by discovering which name was employed first by competent authorities. I could make a shrewd guess that *palmatum* was the original name, but facts are wanted. Thunberg seems to have used the name *palmatum* many years ago, according to Loudon, and doubtless it will be necessary to go back more than fifty years to settle the question, new as many fancy these Japanese Maples to be.—*Rural New Yorker*.

Large Hawthorn.—We have a fine Hawthorn tree growing in the park here, the best, indeed, I have ever met with, and different from all other Hawthorns, inasmuch as it has a fine pyramidal shape and large foliage. Even when bare of leaves it is a fine specimen; its blossom is single white like that of the common Hawthorn, but, as I have said, the habit is different from that of all others growing around it. The height of the trunk is 6 ft.; circumference at 1 ft. from the ground, 6 ft.; spread of branches 30 ft. one way and 36 ft. the other; height from 35 ft. to 40 ft.; age fifty years, or rather more.—W. DIVERS, *Wierton, near Maidstone*.

Welbeck Abbey.—The grounds at Welbeck seem to be literally undermined. Extending in all directions from the Abbey are burrows or passages; not mere borings, but lofty, spacious passages, brilliantly lighted by costly apparatus for letting in sunlight, and, where sunlight cannot be admitted, by lights from gas. By an underground passage we come to the celebrated riding school, the like of which is not to be found in Europe, or elsewhere in the world. It is entered by a trap-door, opened by means of a curiously-designed crank in the passage. In the days of the Duke of Newcastle it was used as a riding school; now it is a magnificent museum of art over 180 ft. in length. Hundreds of pictures are arranged—not hung—round the gallery, and piled in stacks on the floor are thousands of volumes of books, some modern, and many old, rare, and valuable. The floor of this gallery is of Oak, and the ceiling is made to represent a brilliant midsummer sky. Mirrors in profusion are placed about, and light is shed from four chandeliers suspended from the roof, each weighing a ton. This apartment is lighted up by over 2000 gas lights, and when all are illuminated the effect must be extremely brilliant. There are some miles of passages under the grounds. One extends from the Abbey half way to Workshop; another was used only by the Duke of Portland. The passages are all broad enough for three people to walk abreast in them, and pleasant to walk in. The library, like the picture gallery, is underground, and is the work of many years. It is divided into five large rooms, and so arranged as to form, when desirable, one very large room. This library is 236 ft. long. Another immense and superbly constructed room has been erected underground. At one end it is approached by a spiral staircase, and at the other by subterranean passages. Church or ballroom? It would do admirably for both. It was begun five years ago, and is left in an incomplete state. There are many of these rooms at Welbeck. They are free from draughts, admirably lighted, magnificently decorated, and all very costly. Comparatively few outbuildings are to be seen. The most remarkable is the new riding school, a building of gigantic proportions and of extraordinary beaut.

The walls are of solid stone, and the roof of wood, iron, and glass. It is nearly 400 ft. in length, and 100 ft. wide, and divided into a great centre and two aisles. The central department is decorated with a frieze of painted brasswork representing birds, beasts, and foliage, and of perfect workmanship and elegant design. It is 50 ft. high, and lighted by 8,000 gas jets. Here the Duke took pleasure in seeing his horses exercised. The "works" are marvels. He employed constantly upon them over 2,000 workmen. In fact, Welbeck was like an industrial village.—*Sheffield Telegraph*.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 16.

At this, the last meeting for this year of the Fruit and Floral Committees, the following First-class Certificates were awarded:—

Oncidium Edwardi (Buchan).—A rare and newly-introduced Orchid, reminding one of *O. ornithorhynchum*, but the flowers are larger and of a deeper shade of colour, with a yellow crest on the lip. The flowers, moreover, emit a powerful and very agreeable perfume resembling that of Violets, which materially enhances their value.

Cyclamen Baroness Burdett-Coutts (Smith).—A fine variety with pure white flowers of large size, exhibiting great substance and breadth of petal. The foliage, too, is handsomely marbled with silvery markings.

Chrysanthemum M. Lemoine (Jackson).—This novelty represents a medium-sized Japanese variety possessing the peculiarity of two colours; the outermost florets are yellow, and the inner are of a deep bronzy-red. The contrast of these colours is very striking, and renders the blossom very effective.

One of the most attractive features of the meeting was the magnificent group of Cyclamens, which were shown by Mr. H. B. Smith, Ealing Dean Nursery. Every plant shown was well grown, and the whole group comprised a great variety of colour from the purest white to deep purple. Besides the variety Baroness Burdett-Coutts mentioned above, there was another variety named Earl of Beaconsfield, which represented a blush-tinted blossom of large size and fine form, having a rich crimson base. To these a silver medal was appropriately awarded. Mr. Ollerhead, gardener to Sir H. Peek, Bart., M.P., Wimbledon House, exhibited a group of the ordinary Poinsettia, with a smaller number accompanying it for comparison named *P. pulcherrima rosea*. The colour of the bracts of the latter were a shade or so lighter than the ordinary kind, but they were certainly not rose-coloured, and, moreover, did not present such a bright cheerful appearance. From Mr. Miles, West Brighton Nursery, Cliftonville, came a dozen or so of plants of a fine scarlet zonal Pelargonium named West Brighton Gem. It has a good compact habit and apparently very floriferous, and a cultural commendation was accorded to the exhibitor. Mr. Cannell, of the Swanley nurseries, sent some well-grown examples of White Vesuvius Pelargonium, which well exemplified its high merit as a decorative kind. One of the plants bore unmistakable evidence of its origin by having a truss of scarlet flowers produced on the same branch as the trusses of white pips. Mr. Cannell also showed half-a-dozen trays of cut trusses of the leading varieties of zonal Pelargoniums, which were highly attractive; also blooms of *Dahlia imperialis*, and a beautiful *Salvia* named Pitcheri. Mr. Green exhibited, from Sir George Macleay's garden at Pendell Court, Bletchingley, cut blooms of the rare *Dahlia Maximiliana*, which is probably the first time that it has been exhibited. Allusion is made to this plant in another column. Mr. Green also showed a very finely-grown *Saxifraga valdensis*, one of the crustaceous-leaved kinds. The plant forms a dense cushion-like tuft, fully 8 in. in diameter. Colonel Trevor Clarke showed a flowering plant of the Scarlet Pine-apple, doubtfully named *Ananassa bracteata*, but which was apparently *Pouretia flexilis*. It has long scarlet central leaves and a tuft of somewhat inconspicuous flowers. It is a showy plant, and recommended for general cultivation, on account of its easy culture and low temperature in which it will thrive. Mr. Noble exhibited a stem of *Lilium giganteum*, measuring 13 ft. high, and bore during the past summer twenty-two flowers. It grew in his nursery at Bagshot in a prepared border in the open air. Mr. J. Wiggins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, exhibited some new varieties of Cyclamen. One, named Improved Purple Gem, was an unusually deep purple flowered variety; the other was *Crimson Model*, a fine novelty, with blossoms of a pleasing brilliant tint. The same exhibitor also showed a collection of cut blooms of Chrysanthemums, consisting of the Incurved,

Japanese, Pompon, and Anemone-flowered sections, and all of which, notwithstanding the lateness in the season, were excellent examples of skilful culture. A similar contribution came from Mr. J. W. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston-on-Thames, and were also well grown specimens. Messrs. Jackson & Son, Kingston, exhibited four varieties of Japanese Chrysanthemums, viz., *Meg Merrilees*, a fine yellow kind; *Incomparable*, with bronze flowers; *Middle Moulles*, with pure white; and *M. Lemoine*, mentioned above, which was awarded a certificate. Mr. George, Putney Heath, sent a well-flowered plant of *Abutilon Rose Queen*, with blossoms of a rich orange tint veined with crimson; and Mr. Balchin, Hassock's Gate Nursery, Keymer, exhibited *Bouvardia Dazzler*, a variety much in the way of *Hogarth*, but apparently with larger flowers. In addition to the *Oncidium Edwardi* mentioned above, Mr. Osborn, gardener to H. J. Buchan, Esq., Southampton, sent a plant of *Odontoglossum Lindenii*, a rare but not very showy species.

Fruit and Vegetables.—The former was more plentiful than usual on this occasion. The chief point of attraction was the huge bunches of Gros Guillaume Grapes exhibited by Mr. Roberts, gardener to the Countess of Charleville, Tullamore. The bunches weighed respectively 22 lbs. and 20 lbs., and were over 2 ft. in depth and as much across. Both bunches were grown on one rod, and the Vine from which they were cut, has in four years produced 7 bunches weighing in the aggregate 126 lbs. 11 oz. Some excellent examples of Grapes were shown also by Mr. J. Wallis, gardener to the Rev. Walter Sneyd, Keele Hall, Stafford, consisting of Golden Queen, Black Alicante, Gros Colmar, Black Morocco, Barbarossa, Lady Downe's, &c. A silver medal was recommended for this collection. Mr. Atkins, gardener, Lockinge Park, Wantage, contributed a similar collection, consisting of excellent bunches of Muscat of Alexandria, and the same exhibitor also showed a dozen dishes of Apples and Pears, several of which were seedling varieties. Some fine smooth Cayenne Pine-apples were sent by Mr. Goodacre, Elvaston Castle, Derby. A cultural commendation was accorded to Mr. Hinds, Canford Manor, Dorset, for excellent dishes of Tomatoes, and a sample of a fine late Pea (Hallamshire Hero) was sent by Mr. D. Abbott, Sheffield.

ANSWERS TO CORRESPONDENTS.

Hardy Herbaceous Plants.—I am about to fill a number of oblong beds, 12 ft. by 16 ft., with the above plants, preference being given to those varieties that are most useful for cut flowers. The soil is a good one, but, owing to the position of the beds it is necessary that the occupants should not exceed 3 ft. in height at the most. Will you kindly give me a list of the most suitable plants for the purpose?—H. J. C.

			W. G.]

Raising Seedling Briers.—*Rosa*—Gather the hips of the Dog Rose as soon as ripe, about the end of October or beginning of November, choosing those that are long-shaped, and neglecting those that are of a rounder form. Open the hip and collect the seeds; rub them a little, and winnow or sift them so as to get rid of the down that adheres to them. Next throw them into a vessel of water, when the good seeds will sink and the bad float. Collect those that are good, and having mixed them with sand, store them in a pot covered over with a piece of glass, to protect them from mice till wanted. Sow in favourable weather during the months of November and December, or in the spring. Prepare a bed, rake over the surface evenly, and on it spread $\frac{1}{2}$ in. of sand, smoothing it with the back of a spade; then sow and cover the seeds with $\frac{3}{4}$ in. fine earth. To protect them from frost, and also to hasten their growth, it is well to spread over the whole bed about 6 in. of dried leaves, to be removed about the beginning of April, if weather permits. The young plants should appear above ground in April or May, and by the end of October will be well grown with shoots 2 ft. or 3 ft. Thinning and transplanting must be attended to as the plants grow.

Celery Maggot.—*K. T.*—These, when fully grown, descend into the earth, where they remain in the chrysalis state till the following spring, when they

appear in the form of flies, and, in due course, deposit their eggs on the leaves of the Celery plants. The best remedy is to crush the maggots between the finger and thumb as soon as they appear. Sprinklings of soot along the rows help to keep the flies off, perhaps by making the plants distasteful to them. Watering with a weak solution of Gishurst Compound and Tobacco has been recommended, and is worth a trial (2 lb. of the former and 1 lb. of the latter to a barrel of water, and when thoroughly intermixed to be poured over the foliage with a rose pot). Trying to stamp out the pests by burning plants or leaves effected is also a good plan where it can be carried out.

Double Grafting.—Allow me to say that I had occasion a few years ago to graft a Prince Albert Pear growing on a southern wall, the fruit of which was useless for dessert. Amongst other sorts some grafts were taken from an espalier tree of the Seckle. This year grafts of the latter have borne fruits quite three times the size of those generally grown on the espalier, and of the richest colour. A few weeks ago a dish of these Pears was exhibited at our local show, where they were seen by several practical gardeners, all of whom pronounced them to be much superior to any which they had before seen of that variety.—J. ALLAN, *Ashurst Park, Tunbridge Wells.*

Adiantum Farleyense.—M. P.—You will find directions for cultivating this in another column of to-day's GARDEN. Of the white deposit on the leaves kindly send us specimens.

Books.—*Cosham.*—There is no good English book that we know of on practical nursery garden work. *Sub.*—Quin's "Garden Receipts" contains a chapter on skeletonising leaves.

Names of Plants.—*B. G.*—3, *Adiantum reniforme*; others next week.—*W. B.*—*Rhannus alnifolius*.—*F. N. R.*—*Antignon guatemalensis*.—*F. G.*—1, *Oncidium cheiroporum*; 2, *O. bracteatum*; 3, *O. crispum*.—*C. B.*—The pink flower is *Barkeria elegans*; the other wasteo much damaged to recognise.—*S. D. T.*—1, *Retinospora plunosa*; 2, *Abies* sp., but cannot name correctly from such a scrap; 3, *Thuja gigantea*; 4, *Cryptomeria japonica*.—*Decon.*—1, *Passiflora princeps*; 2, *Lasiandra macrantha*.—*R. Q.*—1, *Libonia floribunda*; 2, *L. perhosensis* (these are distinct plants); 3, *Justicia (Peristrophe) speciosa*.—*Enquirer.*—Your specimens damaged beyond recognition; they should be sent in a strong box.—*C. J. P.*—1, *Thunbergia laurifolia*, a stove climber; 2, a species of *Ipomoea*, but cannot name with leaves.—*Ferns.*—1, *Nephrodium molle*; 2, *Davallia dissecta*; 3, *D. Mooreana*; 4, *Asplenium bulbiferum*.

Questions.

Questions Respecting Roses.—I. Which are the three most perfect Roses as regards form, substance, shape, habit, and scent in the following colours:

A. Hybrid Perpetuals and Bourbon Roses.

a. Pure white. b. Tinted white, blush and flesh colour. c. Pale pink and light rose. d. Bright pink and deep rose. e. Carmine. f. Scarlet and vermilion. g. Purple and crimson. h. Dark crimson, brownish and blackish maroon. i. Violet. k. Striped.

B. Teas and Noisettes.

l. Pure white or slightly tinted. m. Bluish and pink, rose. n. Tinted pink and rose. o. Pale and bright yellow. p. Yellow tinted.

II. Which are the three most beautiful Moss-Roses?

III. Which five varieties of Roses are the greatest favourites and the most generally cultivated in any particular district?

IV. Which five Roses distinguish themselves especially? a. through their uninterrupted blooming; b. through superior scent; c. through their hardness.

V. Which five Hybrid Perpetuals are the freest and most abundant bloomers. a. for the summer; b. for the autumn?

VI. Which are the ten best Roses for forcing?

VII. Which five varieties are best adapted for room cultivation?

VIII. Which are the three most beautiful pillar Roses?

IX. Which ten novelties from 1873 till 1878 are of such remarkable beauty that their cultivation and distribution can be recommended without the slightest hesitation?

X. Which are the best ten English raised Roses?

The aim of this list is to reduce the four or five thousand different varieties of Roses at present grown in gardens to a limited number of really valuable ones only. All answers should be sent post free to my address and be accompanied with the distinctly written signature and full address of the sender in order to make it possible to communicate the result to him. To each variety should be added if possible the name of the raiser and the year of its introduction. The printed result of this election of Roses will be communicated gratis and post free to all horticultural papers and correspondents who have taken part in it.—FRIEDRICH SCHNEIDER, President of the Horticultural and Agricultural Society at Wittstock a/D., Germany.

TAILED RADISHES.

AMONGST the novelties exhibited at the great International Horticultural Exhibition of 1866, few things attracted more attention as such than the group of *Raphanus caudatus*, or Long-tailed Radish, exhibited by Mr. Bull. Plants in pots some 3 ft. in height, tied up to stakes and bearing some three or four pods of an irregular appearance, from 18 in. to 20 in. in length, constituted a novelty, which it was stated was destined to supersede root Radishes of all kinds, and render us no longer dependent upon crops that were uncertain, and good only at specific seasons. Like many other introductions, however, from which much is expected, the Rat-tailed Radish has done neither of these things. Nevertheless there is much in the lengthy and curious seed pod to render it attractive to the palate, as it is, when young and produced by quick growth, sharp, crisp, and brisk, tasting very much, indeed, like the veritable Radish itself, but of course always lacking that fleshy character that is inherent in our favourite breakfast root. The *Raphanus caudatus*, however, was not an absolute novelty in 1866, as it was first introduced into this country in 1815, and is a native of Java. It may be grown freely in the open air in summer, sown in rows thinly, and the plants, as they grow, should be supported by sticks to keep the pods from the ground. It

may also be had in early spring and late autumn in pots, if sown and grown so as to produce fruit at either of these seasons.

As an edible product, however, this Long-tailed Radish is inferior in several respects to the pods produced by common Radishes, and especially to the pretty and most abundantly produced pods of the Long White Californian Radish. These, which are about 2 in. long, including the short tail or pointed end, are, when young, crisp and pleasant eating, and offer the best possible substitute for the root Radish that could be obtained during hot dry weather, when the true Radish is usually tough and flavourless. These short-tailed pods are also most acceptable for pickling purposes, either mixed with other vegetables or employed alone; and being naturally of a pretty green hue, they are far more presentable than many things of a similar character. The Californian Radish is perhaps the strongest grower of all the edible rooted kinds, and therefore produces robust growth and an enormous quantity of pods. As a deep rooter it also retains these longer in that crisp tender state so desirable when eaten green. By sowing seed in August, strong roots may be had that, if lifted and stored in sand or otherwise protected from severe frost, are most acceptable in mixed salads during winter; and the roots not so used, if planted out again in spring, will give a crop of pods early in summer. A sowing made in a row during April will give a large crop of pods in autumn, and, if the soil be deep and rich, will, with frequent gatherings, produce abundantly for a couple of months.

Rat-tail Radish.

All Radishes might properly be designated "tailed," but the term so far has been solely applied to the long-podded section. How many sorts of good root Radishes there are (or perhaps it would be better to say how few) was well shown by the exhaustive trial that was so well conducted at the Royal Horticultural Gardens at Chiswick during the past summer. The report of this trial is well worthy the attention of all young gardeners, and the addition of these few notes upon the Tail-podded kinds will not detract from its merits. A. D.

How to Prevent Lettuces Running to Seed.—A German contemporary says running to seed can be avoided by drawing a knife through one-half of the stem to which the head is attached. The sap—or, as they call it in Germany, the milk—will flow, and rob the head of the power to open; yet enough sap will remain to keep it fresh and growing for another week or so.

A New Pea.—There was exhibited at the Sheffield Chrysanthemum and fruit show (Nov. 24th), a rather remarkable new and white wrinkled marrow Pea, named Hallamshire Hero, and raised by Mr. Abbot. It was shown in a green state, both on the dish and on the haulm, and had been gathered regularly up till the 15th of November. The pods mostly contained ten to eleven Peas to the pod, and these of the largest marrow size. Having been subjected to sharp frosts, they had rather lost their sweetness, but I was assured by those who had tasted the Pea at its best that its quality was first rate. Not long before the show a dish of it had been served up at a dinner provided for the Sheffield Gardeners' Mutual Improvement Society.—J. S. W.

"This is an art
Which does mend Nature: ehanze it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FILMY FERNS.

THE information given (p. 548) by Mr. Neill Fraser is most interesting; the Killarney Fern (*Trichomanes radicans*), *T. reniforme*, *Hymenophyllum demissum*, and the solitary specimen of *Todea superba* which we at present possess are growing in just such a sunken, unheated pit or frame as he describes, the only protection during frost being a covering of bracken, on which bast mats are spread. Last winter 22° of frost were recorded here, and even this winter already these Filmy Ferns have been frozen over and over again, the earth in which they grow being now as firm as a stone, and yet the plants look fresh enough. The greatest care required is to keep the sun from them while in this frozen state. Plants of the Killarney Fern were long ago grown here in holes in the open border, in a compost of peat and Moss, a hand-light being their only shelter, except during severe frost, when loose Fern or an old mat was thrown over them. At Glasnevin one of the most interesting of all the plant houses is that especially devoted to Filmy Ferns and their allies. These plants, like most aquatics, resist frost wonderfully well.

Mr. Fraser's recommendation ought to induce many to attempt the culture of these delicate Ferns under glass shades in the dwelling-house. Mr. A. Balfe, of this city, has a healthy Killarney Fern growing on pumice stone, &c., in a small pan covered by a glass shade, and this plant, which is in excellent condition, has been an object of attraction and interest to all who have seen it during the last twenty years. Plants like these are of interest to all, and that their beauty is permanent the above reference will abundantly show. A specimen of the New Holland Pitcher Plant (*Cephalotus follicularis*), also grown in a small pot, plunged in a larger vase, and covered with a glass shade, tilted so as to allow of ventilation, is a worthy companion to the delicate tracery of the Killarney Fern. Both plants grow thus well in the ordinary temperature of a drawing-room, a warm covering being thrown over the glasses during very cold nights. The idea of offering prizes for Filmy Ferns is an excellent one, and would no doubt soon be the means of inducing many to take up their culture. Our stock of *Todea superba*, as I have said, is vested in one fair-sized specimen, or I should be glad to try it under a glass in a shady window and with every confidence of success.

F. W. B.

Ball's Bridge, Dublin.

HELIOtropES AND THEIR CULTURE.

HELIOtropES, sweet scented and beautiful as they are, are well worth the attention of all who have a greenhouse and a little heat at command. They are favourite market plants, and wonderfully well they are grown in the form of compact little bushes, covered with flowers, in 5-in. pots. A good way of growing them is as follows: About the end of July procure some good soft-wooded cuttings, making them like those of other soft-wooded plants, then insert them in pots or pans in a mixture of light soil and silver sand; place them in any close, shady frame, keeping them moderately moist, and they will soon root. When this happens pot them off into small thumb or 3-in. pots, using good light soil, and replace them in the frame. Keep the latter close for a few days, and then give plenty of air on all favourable occasions. As soon as the little plants have grown about 3 in. long, pinch off the tops of the shoots, which will cause them to break freely and form pretty little bushes. As soon as possible shift them into large sized pots, and keep a sharp look-out for green fly and also for red spider and thrips, to all of which they are subject—syringing with Tobacco water; this is better than fumigation, as that is apt to injure the foliage. About the end of September place them in their winter quarters at the warmest end of a greenhouse, and in about a month a portion of the plants may be moved into their blooming pots (5-in. ones), using on this occasion a somewhat heavier soil, and well draining with potsherds; the remainder should be repotted at various times so as to keep up a good supply of fresh plants.

The principal point to be attended to in their winter management is never to allow them to become dry at the root, and to prevent all cold draughts of air from striking them, keeping them comfortably warm, say in a temperature of from 50° to 55°, otherwise they become sickly and stunted, lose their leaves, and become of little value, as the great beauty of the plant, in addition to its

flowers, is the foliage, and, like the Fuchsia, if it once loses this it cannot be replaced. Syringe occasionally with Tobacco water, which will keep down insects. About Christmas the earliest plants may receive their final stopping, and be encouraged to grow on as much as possible. A little weak soot-water is very beneficial to them, and they should be kept near the glass.

About the end of February they will require tying into shape; place one stake in the centre, and loop the branches round it in the form of a compact little bush. March having arrived, when the sun becomes bright, a little shade for a few hours in the middle of the day is beneficial. Give abundance of water at the roots, and ply the syringe freely with clean soft water to the branches. Early in April they will be in great beauty, and may be removed to any place which they are required to decorate.

Young plants coming on will require, in all respects, similar treatment, and with judicious management *Heliotropes* may be had in bloom nearly the whole year round. One of the best kinds in cultivation is still the sort called Florence Nightingale.

HENRY BAILEY.

Fuchsia Tom Thumb.—I am afraid this term is a general one applied to diminutive forms of various genera of plants. The Fuchsia that in these parts has within the last twenty years assumed the above name is one that I have carried from place to place for above thirty-five years. It is not half the size of the one represented (p. 561). My pigmy I first obtained as Thompson's *pumila*; keeping out of sight the species *microphylla* and *thymifolia*, it is the neatest and smallest of all Fuchsias. Many years ago there was a very small Fuchsia, similar to the one depicted, known as *serratifolia*, years before the large one of the fulgens type came into notice. It seems strange that most of the old Fuchsias, such as *coccinea*, *gracilis*, *conica*, *globosa*, *Thompsoni*, *corallina*, &c., should be in confusion as to their specific characters, being as they are often assimilated as one or hybrids; even the true Fuchsia *coccinea* is a plant not often seen. The labours of the hybridist must always be a perplexity to the scientific botanist.

—THOMAS WILLIAMS, *Ormskirk.*

Anætochili.—Mr. O'Brien seems to have struck the happy medium as regards the culture of these plants, by not subjecting them to the excessive heat usually given them, and by steering clear of the cold treatment formerly advocated by a few who have tried it and failed. At the Pine-apple Nursery there are about twenty-four varieties of *Anætochili* and *Goodyeras* all in good condition. The plants are in a case in a warm house, on a side where there is a little bottom-heat, but a false bottom is put in the case, so that the plants have the advantage of being brought near the glass, and at the same time have a cold bottom to stand on. Mr. O'Brien believes that keeping *Anætochili* close and hot at night oftener kills the plants than anything else.

Odontoglossum hebraicum.—This rare *Odontoglossum* is now in flower in the Pine-apple Nursery. Its blossoms are somewhat similar to those of *O. Andersonianum* in size, but in form approach more nearly to *O. navium*. The petals are lemon-yellow, nearly white towards the middle, spotted with brownish-scarlet, the dark yellow flush at the base of the lip, and the snow-white column giving the whole an attractive appearance. Its transparent texture will make it a valuable decorative plant. The flowers are strongly cinnamon scented.

The Gladwin (*Iris fœtidissima*).—Quantities of this old fashioned British plant are now coming into Covent Garden Market. The brilliant orange-red seeds which line the inner surfaces of the pods render it very effective for room decoration, &c., at this season, and it is also extremely useful in flower borders. It grows vigorously in damp places, and the variegated leaved kind is well known as a handsome plant, both for the open garden and also for indoor decoration, where it has a fine effect under artificial light.

Wild Autumn Berries.—There are several wild fruits which ripen in autumn, and which are very pleasing when employed for home decoration. The ripe fruit of the Barberry is gathered quite largely for preserving; but it is also useful in an ornamental point of view. A long branch of it with its clusters of bright red berries hanging upon their long stalks, is a "thing of beauty," and when arranged with autumn leaves and dried Grasses, is a joy through the winter to every eye that sees it. In pleasing contrast with the dark-scarlet fruit of the Barberry is the Red Cedar, with its dark evergreen branches, sprigs of which, when full of lead-coloured berries, form a pleasing element in house decoration. For red, again, the Winter-berry, which is better known as Black Alder (*Ilex verticillata*), is one of the most attractive shrubs, with its profusion of intensely bright scarlet berries, which cling tightly to the slender branches. The common Sweet Brier (*Rosa rubiginosa*) and other wild Roses, furnish bright and attractive scarlet hips—they are not properly berries—which are well worth the gathering, as are also

those of garden Roses. The Sumachs bear large dense clusters of small scarlet-crimson or purple berries. The Stag's-horn Sumach (*Rhus typhina*), and the smooth Sumach (*Rhus glabra*), are both common, and their berries differ in colour with their degree of ripeness. A few of these clusters help to set off the green of the Cedar. Among many others, there still remain two kinds which should not be overlooked. The Burning-bush or Spindle tree (*Euonymus atropurpureus*) is a tall shrub which bears deeply four-lobed, light-red capsules peculiarly attractive, hanging as they do on long slender stems. These soon open and expose several seeds, each of which is enveloped in a dark red pulp. More brilliant than either of the above is the Wax-work or climbing Bitter-sweet (*Celastrus scandens*), a woody climber, which is beautiful as regards foliage, but in autumn, when the orange-coloured pods throw open their three valves or parts, and expose the scarlet pulp which surrounds the seeds, they are exceedingly attractive. In the vicinity of villages and cities, scarcely a pod is allowed to ripen; they are gathered by boys and others, who sell them in little bunches on the streets.—*American Agriculturist*.

Varieties of *Lælia anceps*.—Among the large importations of this Orchid which Mr. Bull received some time ago, there has been several very distinct varieties. In addition to the pure white-flowered kind mentioned last week, we saw, a day or two since, another lovely variety in flower, which is quite unlike any we have yet seen. Its flowers are about the size of those of the type, with the sepals pure white, the petals a delicate soft blush tint, and the lip of a rosy hue crested with gold.

***Habrothamnus fasciculatus*.**—Though this is by no means an uncommon plant, the extreme beauty of the large specimens of it in flower at the present time that are planted out in the Temperate House at Kew renders it necessary to direct attention to it as one of the most valuable of greenhouse plants for winter decoration. Its long clusters of deep pink blossoms are highly ornamental, and when they are accompanied by bunches of rich carmine berries, the effect is thereby much enhanced. The unusually long time during which it continues to produce flowers is another point in its favour, combined with the simplicity of treatment required by it. *H. elegans* and *H. corymbosus* are also desirable kinds, but the species under notice is decidedly the best.

***Acacia retinodes*.**—This is one of the earliest flowering of the hosts of species now in the Temperate House at Kew, its pretty pendulous branches of sulphur-coloured flowers, produced early in November, rendering it a valuable subject for cutting from. Grown in the ordinary way in pots, and placed in a cool greenhouse, it is very effective, and it will continue to flower throughout the winter. Many of the other species at Kew will shortly be in flower, and so give the house a cheerful appearance.

***Tigridia conchiflora*.**—We understand that Mr. Stevens, King Street, Covent Garden, has received a large consignment of this showy bulbous plant to dispose of shortly. Though scarce, and by no means so plentiful in this country as the other Tiger-flower, *T. Pavonia*, it is equally gay and attractive, the large bright orange-yellow flowers being copiously spotted with crimson. It requires similar treatment to *T. Pavonia*, and it is quite as floriferous, especially when planted in favourable positions.

Scotch Champion Potato.—We omitted to mention in our report of the last meeting of the Royal Horticultural Society that the committee awarded a first-class certificate to this Potato, which was shown by Messrs. James Carter & Co., High Holborn, on account of its good quality and disease-resisting property.

Chinese Primulas.—Messrs. Cannon and Reid, of Aberdeen, send us blooms of a pretty strain of Primula, the colour of which is a delicate rose, with a distinct yellow eye. The flowers, too, which are large, have finely fringed margins.

Keeping Apples.—Mr. B. Hathaway describes, in the *Michigan Farmer*, his mode of keeping Apples. Those which incline to wilt, like the Russets, are put in barrels. The more juicy sorts, as the Northern Spy and Greening, are placed in crates, where they will have more air. The Apples are stored in an outside cool place till freezing weather approaches, when they go to the cellar. This holds 1500 bushels, and leaves space for work and passages. The fruit room occupies the whole cellar, which admits of better ventilation than if a portion is partitioned off at one side.

***Fontanesia Phylliræoides*.**—I note this shrub not only because it is a valuable and neglected plant, but because it is somewhat remarkable for being tender in England and apparently hardy in America. It is related botanically to several well-known shrubs, like the Forsythia and Lilac, and has attractive foliage, not unlike some varieties of those genera. The flowers are yellow and not specially striking, but they bloom in August, which is a decided advantage. With these qualities in view, this *Fontanesia* should be borne in mind by lawn-planters.

COUNTRY SEATS AND GARDENS OF GREAT BRITAIN.

PARK PLACE.

ENGLISH gardens are often on level ground or embosomed in valleys, and all the better for it, perhaps, on the whole. But the hills that, so far as building and making gardens went, were neglected by our forefathers are now here and there valued as they deserve to be; and very charming it is after lazily admiring the many pleasant lawns and gardens along the Thames and in the valley to creep up these high river hills, and then, coming out on the Grassy top in the cooler air, see one of the loveliest and most extensive of English landscapes. High downs, yellow fields of corn, green meadows, open breezy lawns in the foreground, and bold Cedars near, were parts of the elements of a picture—as fair as can be found in any country. When the foreground is made up of a park in which plenty of Grassy breadth is preserved, and also stately vegetation and gradually receding views at many distances far beyond the river, as well as the river scenery, it is then there is a combination of beauty which is rarely to be met with.

This is indeed one of the most naturally beautiful and picturesque places on the banks of the Thames. After crossing the river by means of a fine stone-built bridge, the whole distance to the house is uphill, but after the first gate lodge is reached, we have a well-contrived drive that winds its way through the hanging woods for a considerable distance. It is somewhat circuitous, the object being to make its ascent as easy as possible. The frequent views obtained of the distant country make its course cheerful and interesting. On emerging from the woods an open view of very wide extent and variety suddenly presents itself, and the house is soon afterwards reached. Its principal front faces the river, but it stands nearly 300 ft. above it. From this point the views in almost every direction are very fine, extending over large tracts of Surrey, Hants, Berkshire, Buckinghamshire, and Oxfordshire.

This estate was formerly the residence of Frederick, Prince of Wales, and of another Prince of Wales, afterwards George IV. General Conway then purchased it, and to him it owes many of its most interesting features. After his death, Lord Malmesbury became its owner, and made many alterations and additions to it. It subsequently came into the hands of the Maitland family, who occupied it for many years, and likewise did much to improve and adorn it. For a period after this, it became somewhat dilapidated, when it was purchased by its present owner, Mr. John Noble. Within a few years the house has been almost entirely rebuilt, considerable additions in the French chateau style having been made to it. Mr. Marnock, who laid out Mr. Noble's other place at Berry Hill, has well used his great experience and knowledge in the improvements at Park Place, everything tending to promote its beauty, whether considered in relation to architecture or gardening, having been done thoroughly. While having, however, so much to praise about the place, there is one feature which seems to us not desirable for imitation—a mosaic flower garden formed after the outline and pattern of a vase. Such an object may be skilfully carried out, and may excite admiration for this character from persons who do not consider how such a stamped garden affects the view from the house of the beautiful things around and beyond. The hard and very artificial character of this mosaic garden makes it far from attractive to those who do not care for elaborate geometry out of books or patterns.

In addition to ordinary "bedding," Alpine, and sub-tropical gardening, there is here a rich collection of herbaceous plants. Spring gardening is also extensively practised, no empty beds being seen either in winter or spring. The glass department, like other parts of the establishment, is on a large scale, there being few things worthy of cultivation that do not receive attention. Long ranges of Vineries and other fruit houses produce for their age very heavy crops. The whole of the Vines were raised on the place from eyes struck in turf on the system recommended by Mr. Wm. Thomson, and with most gratifying results. A mode of growing Bananas (*Musa Cavendishi*) is practised here very successfully. They are planted out in an ordinary

the glasshouses and other buildings are occupied with plants adapted for such positions, and although sometimes with varying success in respect to hardiness, yet, on the whole, with satisfactory results.

The wants of the young gardeners employed at Park Place have not been overlooked. A picturesque building has been erected for them, with large, comfortable sitting-room, kitchen, and lavatory lighted with gas, and a separate bed-room is provided for each. Adjoining this is the garden office and Grape room. There is also a garden library, and a botanical class is held here in connection with the Science and Art Department, the gardener (Mr. Stanton) being one of the Department Science teachers. At the last examination held

In the Gardens at Park Place ; view from Grove.

house, and fruited regularly and quickly ; the fruit is excellent in flavour, wholesome, and forms a valuable addition to the dessert. The clusters of pips produced vary in weight from 35 lbs. to 45 lbs. Several other tropical fruits are also ripened here. Plants are very extensively grown, and occupy the greater part of the glass. They are not grown as specimens for exhibition, but of a size to make them useful for conservatory and general decoration. *Eucharis*, *Anthuriums*, *Gardenias*, *Stephanotis*, and winter-blooming plants of all kinds are grown in quantity. Upwards of 600 Tree Carnations of the best varieties are grown here for winter bloom and for bouquets. All the best climbers are planted out, and thus treated form a striking feature, particularly in the tropical house, where they are allowed to ramble to a certain extent at will about the roof. All bare pieces of wall on the outside of

in the gardens ten certificates and three Queen's prizes were awarded to the young gardeners.

The conservatory attached to the house is of considerable size, and may be said to form a part of the fine suite of rooms with which it is connected. The principal object was to unite a house for plants with an enjoyable room, a combination not always accomplished with satisfaction, but in this case eminently so. As a plant-house, experience has shown that many, both fine-foliaged and flowering, plants will succeed in it, although considerable labour and attention are necessary to maintain its effectiveness ; and, as an enjoyable room it is as much used as any in the house. It is capable of being lighted with sixty-three gas jets on certain occasions, but in an ordinary way much fewer are used. These lights, being considerably above the plants, do not affect them as

might be supposed. The effect of this house, though much better than that of the ordinary conservatory, is not quite so good as that of houses where the vegetation is planted out in a picturesque manner.

A few words about the water supply may be interesting. That for the garden is most complete and convenient. Paradoxical as it may appear, yet although each separate house has its tanks, there is not a single tap connected with the arrangement, each tank fills itself and cannot overflow. The water supply to the house comes from a great depth out of the solid chalk, and although destitute of all organic impurities, is of course what is termed hard water. To remedy this, Dr. Clark's softening process has been adopted with great success. This consists in an admixture of a proportion of lime-water with the natural hard water. The former extracts the chalk, and precipitates it to the bottom of the reservoirs, rendering the water as soft as rain-water. The pumping is done by means of a gas engine of 2-horse power, which answers admirably and is economical.

The park surrounding the house consists of hill and dale, woods and Grassy slopes, traversed by shady walks, left to a great extent to Nature's keeping. The whole place abounds with wild flowers, and of rare ones not a few, constituting in reality one great pleasure garden. From the river in many places perpendicular chalk cliffs run up and meet the hanging woods and open glades for a considerable distance along its banks. From many of the views the river has the appearance of a large lake, containing here and there little islets, features which add greatly to the beauty and charm of the scenery. In one deep Grassy dell, not far from the house, stands the Chinese Cottage, embowered in Virginian Creeper, and Irish Ivy. In autumn the Virginian Creeper has a most brilliant and charming effect, the bright rich crimson of the one contrasting finely with the dark green of the other.

At another point not far from the raquet court, is a large hardy Fernery and wild garden. Here besides Ferns, are great quantities of bulbs, wild flowers, and such other things as have been found to thrive, all having quite their own way. Its surface is so varied that although it may not be possible to get lost, yet a stranger might have some difficulty in finding the nearest way out of it. In connection with this, are a series of caves cut out of the natural chalk and branching in different directions, one of which forms a subterranean passage of great length, intensely dark of course, but perfectly safe and easy to walk through. This cavern leads suddenly to one of the most lovely spots on the place—"The Happy Valley," a glade sloping down to the river's brink. On the top by the cavern's mouth, is a series of ruins in imitation of a Roman Amphitheatre. Descending the valley, the flanks of which are clothed with Beech, Larch, and Cedars, to near the bottom, the pathway runs under a rugged arch, built of immense unhewn stones and conglomerate, the transport and erection of which must have cost a large sum. It presents that aspect which age alone can give. Passing under the archway, the picturesque boathouse and its surroundings are soon reached, forming altogether from the river a view which few oarsmen fail to stop and admire.

A short distance from the boathouse stands all that remains of the first Lombardy Poplar planted in this country. It was brought here by Lord Rochford, and planted by General Conway. It has withstood for many years the shock of wind and flood, yet, although but a mere shell, one side of it remains, which still shows considerable vitality. In another part of the grounds is the Druid's Temple, consisting of many gigantic stones arranged in cells, the whole having a circular outline. This interesting relic was discovered at St. Heliers,

in Jersey, and presented to General Conway, its then governor, who removed it with great care, and re-arranged it in its original form. From this temple is seen probably the most extensive view on the whole place, through which runs a long reach of the Thames and its valley.

On the lawn near the house stands what is called "the King's Cedar," a tree planted by George III, and said to be one of the most stately Cedars of Lebanon in the country—some, no doubt, exceed it in girth, its circumference being 19½ ft., but for symmetrical growth it is perfect, its branches reaching to the ground. Many other fine Cedars adorn various parts of the grounds, some in groups, and others in the form of isolated specimens.

FLORISTS' FLOWERS AT HILLINGDON PLACE NEAR UXBRIDGE.

IN such a garden as that of Mr. Little, whose name has so long been intimately associated with various classes of what are termed florists' flowers, one may at any season find something of interest. Even in dull December, there was the other day no dearth of flower, for though the Cyclamens, which are Mr. Little's speciality, were not at their best, and the collections of Primulas, Cinerarias, and others were in but an incipient stage of flowering, the well-known collection of Chrysanthemums was still a source of attraction, though many of the finest sorts were somewhat past their best. The houses in which the collections are grown are light and roomy structures, and that which shelters the Cyclamens is a lean-to, 140 ft. long by 10 ft. wide, light, yet strongly roofed with iron. The house is sufficiently heated by a stack of 4-in. pipes, and the plants are placed on benches as near as is convenient to, the glass. Until recently Mr. Little had placed the pots on a trellis, but he found that so much heated air, which was required during the late frosts, circulating so near the plants was very prejudicial to them; he has therefore now placed sheets of zinc on the trellis with a thin layer of coal ashes for the pots to stand on.

The advance which Mr. Little has made with regard to the improvement of the Cyclamen is now well known, and of which his superb "strain" affords ample evidence. It is with respect to the development of richness and variety of colour, together with improving the form and substance of the flowers, to which Mr. Little has turned his attention more particularly; but the exquisite silvery-marbled foliage that has been obtained in his plants is by no means an unimportant feature. In some varieties, the leaves, which are very handsome, resemble in a striking degree the fine variegation of some of the tropical Aroids, such as the small-growing kinds of Peperomia, Pothos, &c. It is a singular fact, however, that the most distinct variegation is restricted to the lighter-flowered varieties; but no doubt Mr. Little will succeed in infusing this character into some of his deep-coloured kinds, which will materially enhance their beauty. Speaking of the colours, I noticed an intensely deep purple-flowered sort—in fact, one might term it a black purple. It is the deepest hue that Mr. Little has succeeded in obtaining, and, as a natural consequence, he values it highly. It is the result of a cross between Ruby, a splendid deep carmine-tinted kind, unfortunately now lost, and Royal Purple, the deepest-hued sort previous to its being supplanted by the novelty under notice. It also possesses form and size of flower, with breadth and substance of petal, which has been aimed at in the hybridising manipulations in this establishment. All the shades of colour-tint yet obtained may be seen here, from the densest hues to the delicate shades of Delicatum and White Perfection, with every possible intermediate tint that can be reproduced by art. Though the collection here of these charming flowers is large and increasing, and contains some excellent specimens, yet it is small compared with the unusually large one which Mr. Little possessed at his former residence, at Twickenham, the fine specimens comprising which were well known at the metropolitan exhibitions, where invariably they occupied a premier position. Some of these plants used to bear as many as 350 blooms, and afforded a fine sight during the many weeks they were in perfection.

The Chinese Primula is another of Mr. Little's favourites, and of this he possesses an excellent collection of well-grown and strong plants, which, in a few weeks, will be a sight worth seeing, for it is evident, by the colours of one or two of the pips that are expanded, that he has a fine strain. One plant in particular is deserving of especial notice, as, in richness of colour, its flowers surpass any I have yet met with. An approximate idea of its beauty may be formed by the flower being described as having a deep orange-yellow eye, encircled by a ring of deep velvety crimson, and with a beautifully fringed outer edge of the richest carmine.

The Cinerarias are fine examples of skilful culture, not merely made-up specimens, but *bona fide* single plants, grown from seed sown last January, and now forming well balanced plants in 12-in. pots. Of these there is a dwarf strain, said to grow only a few inches high, which, if true, will be an acquisition for decorative purposes, especially if it is good in other points. In this house also is a collection of Pelargoniums, a class of plants which here receive much attention, and which are great favourites with Mr. Wiggins, the head gardener; the certificates that have been awarded to various kinds is in itself sufficient proof that the work carried on here with regard to raising new varieties is not in vain. Both the zonal and the show classes, as well as the fancy and decorative ones, are grown here for the purpose of improvement.

Amongst indoor bulbous plants, perhaps there are none that are more satisfactory to grow in a general way than the showy kinds of Amaryllis, of which there are now so many magnificent varieties. Mr. Little's collection of these is unusually large, comprising several hundreds of plants, and these are now being rested in a Vinery, though many are already sending up flower spikes, and several are even in bloom; and this perennial habit of flowering is a characteristic which renders them highly decorative subjects. The system of resting the plants here is somewhat different from the course usually pursued, for, instead of allowing the plants to shift for themselves in some out-of-the-way corner, they are placed tidily on stages near the light, and so arranged that each individual plant may be watered or its requirements seen to when necessary. As a sort of mid-season hobby, between the summer flowering collections and the Cyclamens, the Chrysanthemum is taken in hand in extensive numbers, comprising not only all the leading varieties of more recent introduction, but the best of the older varieties which long ago were discarded by the general grower and the seeker after novelty as unworthy of attention. Many of these Mr. Little rightly considers still unsurpassed in their way. Of course, in mid-December, many of the finest blooms of the best varieties were on the wane; still the later ones made a good show, and will continue to do so for some time. All the sections are well and numerous represented; amongst the finest of the blooms of the incurved kinds I noted Lord Derby and its near ally Prince of Wales, the White and Golden Beverley, Mrs. G. Rundle, White Venus, Queen of England and its yellow form, White and Golden Empress of India, and many other kinds. Of the Japanese sorts were James Salter, Mons. Crousse, To Kio, The Cossack, Gloire de Toulouse, La Nymphé, La Frisure, Cry Kang, Bronze and Red Dragon, &c.

The Pompones are a favourite class here, and certainly they well deserve a place when well grown, and no doubt will increase in public favour. The later varieties were in perfection, and there were still several to expand.

Apart from the collections of florists' flowers, the outdoor arrangements at Hillingdon Place are well designed and very pleasant, owing to the extensive shady walks which are led through well-kept shrubberies; there are also various kinds of Conifers, which thrive here as well as I have yet met with them in the neighbourhood of London. Amongst them are fine examples of *Picea Nordmanniana* and *Pinus*, *Abies Albertiana*, the Decolar, the Atlantic and Lebanon Cedars, *Abies Douglasi*, Hemlock Spruce, various Pines, and others.

W. G.

***Thalictrum adiantifolium*.**—How glad I should be if I could persuade T. minus to run in my garden as described in THE GARDEN (p. 555). The leaves are so lovely at the right stage of growth that I consider no place in my garden too good for it; but it does not spread there, nor have I noticed any tendency to spread in any of the places in which I have found it wild. This distinction, however, between T. minus and T. adiantifolium is very interesting to me, because I have been buying T. adiantifolium wherever I have found it in a catalogue, to try whether I can make out any marked line of distinction between the two varieties. One of the most remarkable instances I know of difference of habit in varieties of the same species in their tendency to run occurs in the Pulmonarias, of which I cultivate what I have generally believed to be four distinct species, differently named by different authorities. The two most distinct of these, both in habit, and leaf, and flower, are those generally known as P. officinalis and P. angustifolia, the latter being truly wild in Hampshire and Dorsetshire, whence I obtained it. I find, however, that Mr. Bentham, in his "British Flora," considers the two as identical, saying that every intermediate form may be found in the south of Europe. I do not dispute the validity of this text, but I cannot understand how the same authority can treat *Orchis latifolia* and *O. maculata* as distinct, as I have found every intermediate form between these growing in the same field, and once sent a bunch of them to a good botanist, asking him to sort them for me, which he confessed he was unable to do.—C. W. Dob.

THE GARDEN FLORA.

PLATE CCXII.—THE CRIMSON-RAYED LILY.

(*LILIUM AURATUM CRUENTUM*).

THIS magnificent Lily, which has been named by Mr. Bull *L. auratum cruentum*, has flowered well this season in his collection at Chelsea. The history of Mr. Bull's specimen is this: An importer of goods from Japan bought twenty bulbs of this Lily at two guineas each—a high price, which shows the estimation in which it is held in its own country, where *L. auratum* costs only a few pence. Only two of the twenty bulbs grew; and these were bought by Mr. Bull. I had the pleasure of seeing the plants in flower when on their way to him, and can vouch for the fact that the annexed plate does not at all exaggerate their beauty. When many bulbs of *L. auratum* are planted different varieties of flower appear, some with a brownish band, named *L. auratum pictum*, others with a nearer approach to the crimson band. I have had this experience myself, and have often heard of the crimson-banded Lily from growers, but once see the true *L. rubro-vittatum* in its glory and all the poor attempts at it are nowhere. There is as much difference between them as between a poor specimen of *L. speciosum roseum* and the true old *L. speciosum rubrum*. The Japanese, well known as skilful hybridisers, have probably been able to throw into *L. auratum* some of the brilliant crimson of the true *L. speciosum rubrum*.

Perhaps a few words on the outdoor cultivation of *L. auratum* in general may be acceptable. I will therefore describe a situation in this garden, where, in the past unfavourable season, *L. auratum* bloomed, not merely well, but with as fine flowers as I have ever seen; and, as the bulbs happened to be some early, some medium, and some late bloomers, we had a long succession of flowers coming out in weather of all sorts. The stems were from 6 ft. to 7 ft. in height, and, not being staked, some of them tumbled about with the weight of their flowers, lying upon the Rhododendrons. The bed was made about two years ago, and has been left undisturbed since. It is situated at the south side on the curve of a long lawn bed of Rhododendrons; but, as across the walk there is a high hedge of trees and shrubs, it is entirely protected from sun and wind. The soil is 4 ft. deep, and was made of two parts good peat, one part road-scrappings (here our road stone is flint), and one part sharp sand. On the north side of the bed *L. Krameri* and *L. speciosum* bloomed well. *L. auratum* may be grown so as to give very late flowers.

G. F. WILSON.

Heatherbank, Weybridge Heath.

Plant Protection.—Next to snow, dry leaves are the most valuable plant protectors we have, and if a small mound of these is packed around the collar or stems, if any, and kept there by means of a few evergreen branches, the heads will be able to take care of themselves. In the case of *Euonymus* and other shrubs of that kind of doubtful hardness, it is a good plan to hang some braeken over their heads, and to keep it in position by sticking a few stout pieces of common Laurel so as to overhang it, which will help to take off its unsightly appearance. Pampas Grass will need similar attention. In 1860 the winter was much like the present in the severe manner in which it set in, and thousands of Pampas were then killed which might have been saved had they only received timely protection. Gorse, where it can be obtained, forms a capital shelter for Tea Roses, as it may be laid about amongst the beds, after they have received a good dressing of manure, in such a way as to render all safe. Plants in borders should have a shovelful of leaf-mould laid around the crowns, which is far better in every respect than cinder ashes, so much in favour now-a-days with many cultivators.—S. D.

LILIUM AURATUM CRUENTUM

GARDENING FOR THE WEEK.

Orchids.

Phalænopsis, &c.—Although plants of *Phalænopsis* undoubtedly do best where they are kept cooler for a considerable length of time through the winter than many growers keep them, still if hung up near the roof in the way in which I have from time to time recommended, during such a winter as we are now having, care must be taken that on severe nights they are not too cold; for it is well to bear in mind that a thermometer placed low down in the house often indicates a temperature half-a-dozen degrees or more higher than one nearer the glass. Still, rather than increase the temperature by more fire-heat to meet the requirements of plants like the above when hung up close to the glass, it will be better to lower them for a time. With the same view such plants as *Saccolabiums*, and all but a few of the less heat-requiring *Vandas*, *Galeandras*, *Angræcums*, and the warmer section of *Aerides*, should, unless where there are the means of keeping them and any others of a similar character in a separate structure, be placed at the warmest end of the house, which will be much better than keeping up a temperature to suit the needs of these alone, which at the same time will have the effect of placing the other occupants under more heat than they require. The necessity for this course will be obvious where Orchids are treated in the way that has been found most conducive to their welfare, by as low a temperature as they will reasonably bear. During severe nights, such as we have lately had, there are two things to be especially guarded against, viz., the over-drying of the atmosphere, where there are no evaporating appliances, resulting from the necessity of making the pipes hotter than usual; and the opposite of too much atmospheric moisture where evaporating troughs on the pipes exist, and care is not taken to see that too many of these do not contain water, particularly where they are cast on the pipes, as with the increased heat requisite to be kept up during hard weather the vapour which they throw off becomes proportionately great. I have frequently seen in the case of inexperienced growers mistakes made by extremes in this way which have done serious mischief, as independent of the harm that generally results through drip from the roof, an atmosphere over charged with moisture, and at the same time warm, invariably tends to excite growth sooner than is desirable.

Calanthes.—The different forms of *Calanthe vestita*, and the other bulb-forming varieties raised from them, will, in most cases, now have done flowering. I have always found these plants to require different treatment after blooming from other Orchids, inasmuch as they suffer if submitted to a correspondingly lower temperature whilst at rest, for it is during this time that the buds at the base of each bulb that are to form the next year's growth are gradually developing, and if kept so cool as not to admit of this process, slowly but continuously going on from the time they have done flowering until subjected to an increase of heat to start them into growth, they always break weakly, and the succeeding year's growth never attains the strength it otherwise would. And I believe one of the reasons why these plants are often seen in a comparatively small, indifferent condition is, that they are thus kept too cool in the winter. The temperature of the warmest house where they have flowered will answer better for them than moving them to cooler quarters. If there is any scale upon them, their being now completely devoid of leaves permits of their receiving a thorough cleaning, which should be done by sponging, not with a hard brush, as the thin cuticle of the bulbs of these plants is easily injured, and when this occurs it frequently causes them to rot. When well managed, these *Calanthes* increase much faster than most Orchids. Their extremely free-flowering disposition, the length of time they remain in bloom, and the adaptability of the flowers, either individually or in whole spikes, for using in the various arrangements of cut flowers, constitute them second to no winter-blooming stove plants; so much so, that I should recommend all who have a warm stove, even where no other Orchids are cultivated, to grow these, for so easily are they managed, that, with a moderate amount of attention, they will do well in an ordinary plant stove.

Dendrobiums.—Very much more may be done in keeping up a continual succession of Orchid flowers all through even the duldest times of the year than with almost any other family of plants; and although it is an effective and beautiful sight to see a large number of species with their most opposite forms and colours in bloom at one time, such may be seen in April, May, and June, where large collections are grown; still with the majority of people this will not compensate for a deficiency through the dull months of the year, when flowers, especially those which last long, like many Orchids, are most valued. Some of the best kinds for winter work are to be found amongst the *Dendrobes*, which, where a sufficient number of species are grown, will in themselves almost encircle the year with their flowers. There are none better for coming on early

in the New Year than the Chinese species, *D. moniliforme*, which, even when kept quite cool after its growth is completed, will now be pushing its flower-buds. If several examples are grown, and a portion of them are now put at the warmest end of the intermediate house or coolest place in the stove, in a few weeks they will open their flowers which, for endurance, either on the plants or when cut, are remarkable. If the plants have been kept quite dry they should be moistened at the roots when put into more warmth. This, though an old subject, has become somewhat scarce, and where it is not grown, and there is stock enough of the nearly allied *D. nobile*, part of which were treated so as to make their growth early, and have had a good rest, some may now be put in heat and brought on into flower; but beginners with this plant need to be very careful in not giving it any water, either at the root or overhead, until the bloom-buds are not only prominent but the flowers visible, as, if suddenly excited by moisture in addition to warmth, many of the buds will go off into growth. The beautiful *D. Wardianum*, with its elegant drooping habit, the flowers equally handsome in a cut state as on the plant, and correspondingly enduring, may also, with enough plants, be had in bloom for almost half the year. Where this species is grown in quantity, some of the earliest matured may be put in heat and brought on into flower.

Cattleya Trianae.—Plants of this class, coming into bloom as they do over a lengthened period sooner or later, according to the time when their growth was completed, and the conditions as to warmth under which they have been placed whilst at rest, may now in some cases be pushing up their flowers. Where these are found to be making progress inside the scape a little water may be given, for they, like other plants, when showing signs of the bloom developing, are better not too long retarded, allowing them to come on slowly. This plant, more than most, is much influenced as regards the duration of its flowers when open, by the treatment it receives whilst they are in course of development, and if hurried during this stage the blooming is much sooner over.

Oncidiums.—The different species of these that bloom in the early portion of the year, and that form their flower-spikes very slowly, after these begin to elongate are better not kept quite so dry at the roots. I have frequently seen those plants, the growth of the flower-spikes of which is very slow, kept in such a dry, parched state whilst in this stage, that they could not possibly be expected to bloom as they ought to do. Yet beginners in Orchid cultivation must by no means suppose that it will do to keep plants that are in the condition described so wet as during the growing season. But there is very much difference between having the roots too wet, and keeping them in the opposite extreme—so dry that the whole plant is shrivelled at the time its energies are taxed in preparation for flowering. Be careful not to allow heat-requiring kinds like the different forms of *O. Lanceanum* to be in too low a temperature for the next two months, or the plants may be lost altogether. The same holds good as regards the West Indian species, *O. luridum guttatum* and its varieties, which will not bear to be kept as cool in the winter as the generality of intermediate house plants with which they are often associated when growing. Some of the best forms of the last-named kind, although they lack the novelty of more recent introductions, and are not so bright in colour as some, yet from the stately character of their bloom-spikes and the persistent nature of their flowers, are better worth growing than many which find more favour.

Lycaste Skinneri.—Where a sufficient number of this useful free-flowering plant is grown it, too, may be had in bloom over a long period during a great portion of the winter and through spring; but to have it in flower in this way over a considerable time, it is necessary to treat the plants somewhat differently as to the warmth given them in the winter. It is essentially an intermediate temperature Orchid, and will take no harm during the winter in a night temperature of 46° or 48°; but to have it in bloom early it is necessary to keep it a few degrees higher than this, and whether the plants are treated so as to get them on in this way somewhat earlier, or kept at the cooler point mentioned, I have never found them to succeed well if the roots are kept so dry as those of some things. Its free growth and profuse disposition to flower with the great difference in the colour of the bloom produced by individual plants, make it one of the most desirable of Orchids to be grown in quantity, even by those who do not cultivate large collections. Strong examples now showing a number of flowers coming up from the base of last year's bulbs, may, if kept as already pointed out somewhat warmer, with the soil in a half-moistened condition, be had in bloom to succeed the earliest now in flower.

Sophrontis.—This beautiful small-growing Orchid, so conspicuous for the colour of its large and brilliant flowers, should be kept tolerably dry after blooming, but not so as to cause it to shrivel too much. The coolest end of the intermediate house will be warm enough for it for a time until the season for its commencing

growth has come, as like most other plants that make growth under the influence of a comparatively cool temperature, it is liable to start too early if submitted to over-much heat during the winter, and I never found it either to make such good growth or flower so well unless it has a considerable rest and does not begin to grow too soon.—T. BAINES.

Flower Garden.

Cold Frames.—The cultivation of hardy plants in frames is an interesting occupation for lovers of choice herbaceous plants, but it is a great mistake to suppose that such are easily grown, and require no attention. I had a look through a small pit containing such plants to-day, and can see two days' work or more in merely stirring the surface soil in the pots, picking out weeds, and removing withered leaves from the plants. It is, however, interesting work, as one can observe, now that the soil in the pots has thawed, what the state of the occupants is, for during several days the soil was frozen through and through. Here we have a few dozens of pots of *Tritonias* and *Ixias*, upon which the frost has had no effect whatever, even although many of them had grown considerably, some of the *Ixias* being quite 3 in. and 4 in. out of the soil. Except the species of *Primula* mentioned last week as having suffered, all the others are sound; and I must say that the points of the leaves of *P. capitata* are injured. There are a few, such as *P. Parryi*, *P. Munroi*, and *P. rosea*, the leaves of which are dead down to the crowns; but, of course, that would happen if there was no frost; the crowns seem quite firm and sound. There are the different varieties of *P. cortusoides* which may be frost-bound all the winter and not suffer in the least. The same may be said of *P. japonica*, the leaves of which are now quite green. Then there is the singular but very handsome *Meconopsis nepalensis*, the outer large leaves of which have been killed, but the smaller ones have formed a tuft of surpassing beauty, and the leaves, which are now very short and rigid, seemed formed to defy any amount of frost. Here is a hardy plant which may be grown and admired for its foliage alone, but it also yields in summer a spike of very beautiful flowers. I cannot say that the rather tender growths of the show and fancy varieties of *Pansy* have not suffered, the growths seem to droop and some of them have quite "fogged" off. The pots are plunged in dry material, and it is certain that where the long stems are killed, new growths will be thrown up from the base. Any work that can be done during severe frost that will forward operations in the spring or summer, when one does not know what to turn to first, should now be attended to. The exhibitor of florist flowers will have plenty to do in preparing his stands and boxes in which the stands or trays are conveyed to the exhibition; they may be painted and varnished, stowing them away when dry where they can be kept free from dust. Labels may be made and painted. Some persons like to write on dry paint, but wet paint is best, and the labels may be painted a second time before they are used. Sticks may also be prepared of various lengths and thicknesses; paint them green, and then dry them and tie them up in bundles ready for use. Pegs for layering *Carnations* and *Picotees* may also be cut out of any branches that may be most convenient. Beech and Hornbeam are amongst the best for this purpose. Failing these, wire, about the diameter of that used for ladies hair-pins, answers well. Galvanised pegs are made and sold for this purpose.—J. DOUGLAS.

Hardy Fruit.

In this, the last calendar of the year, it is but natural that notice should be made of those fruits that have in spite of bad weather been up to the usual average, both as regards quantity and quality, and though as a matter of course the remarks about to be made only apply locally, yet they may serve generally as some slight guide to the inexperienced who may be contemplating fruit tree planting. At least the trees named in the list will possess the merit of hardiness, seeing that we have had frost in every month of the year except July. No kind is mentioned except those which have given a fair average crop, and which are of passable quality. They are as follows:—Apricots—Musch Musch and Moorpark. Apples, dessert—Devonshire Quarrenden, King of the Pippins, Court of Wick, Cellini, Margil, Ribston Pippin, Court Pendu Plat, Cockle Pippin, and Lemon Pippin. Kitchen Apples—Lord Suffield, Hawthornden, Golden Noble, Blenheim, Lord Derby, Yorkshire Greening, Wadhurst Pippin, Kentish Fill Basket, Wellington, Warner's King, London Pippin, Winter Colman, and Hambleton Deux Ans. Cherries—Morellos only, dessert kinds were quite a failure. Currants—Red, White, and Black were all good. Gooseberries—Red Warrington, Companion, Rough Red, Rumbullion, White Champagne, and Whitesmith. Nectarines—Pitmaston Orange and Downton. Peaches—Early Louise, Early Grosse Mignonne, Royal George, Bellegarde, Noblesse, and Barrington. Pears—Williams' Bon Chrétien, Beurré de Amanlis, Flemish Beauty, Brown Beurré, St. Michel Archange, British Queen, Beurré Superfin, Beurré Hardy, Fondante d'Automne, Autumn Bergamot, Beurré de Capiaumont, Comte de

Lamy, Seckle, Swan's Egg, Beurré Diel, Durandean, and Pitmaston Duchess. Plums, dessert—Jefferson and Kirk's; kitchen—Early Orleans, Victoria, Pond's Seedling, and Autumn Compôte. Raspberries were a heavy crop; being moisture-loving plants the incessant rains were in every way beneficial to them. Strawberries—Vicomtesse Hericart de Thury and President; these bore enormous crops. It may be observed that Peaches, Nectarines, and Apricots were well protected from the spring frosts with scrim canvas, and that some of the Pears were afforded Birch spray as shelter whilst they were in flower. The long-continued frost will cause work to fall so much in arrear, that unless forethought be exercised it will be difficult to keep pace with it as soon as the frost disappears. Therefore to avoid such a pressure let all manure and soil wheeling be finished, stakes cut and pointed, labels made, and trees that require it relabelled, nails can be cleaned, shreds cut, bunches of matting for tying, and small twigs for laying in the new shoots of wall trees—these, together with other jobs that will suggest themselves, may all now be done by way of forwarding operations when the busy time arrives. When the air is dry and free from frost open the fruit room ventilators for an hour each day. I find that the fruit this winter soon gets mouldy, which, I suppose, is attributable to the excessive rainfall, for the damp this season permeates everywhere and everything. All decayed fruit should be removed forthwith, and it may be worth while to wipe over the finer Pears with a dry cloth, in order to ensure their better preservation. Easter Beurré and Ne Plus Meuris, two kinds of Pears on which we depend for supplies in January and February, are this year so specky and subject to mould that without thus drying they would fail to keep at all. Winter Nelis, Passe Colmar, Fondante, Van Mons, Bishop's Thumb, and Urbaviste are usually amongst our best dessert Pears, but baving this season failed to ripen they are being used as stewing Pears, and though not equal to the best culinary varieties, such as Catillac, Calebasse, Beurré Bretonnean, and Beurré Rance, they are much approved of for that purpose. So that those who have Pears of any kind which fail to ripen for dessert may find them valuable to eke out a scanty supply of culinary kinds.—W. W.

TREES, SHRUBS, AND WOODLANDS.

JAPANESE MAPLES.

WITHIN the past twelve or fifteen years numerous additions* have been made to the already large list of the genus *Acer* by the discovery of several new species in Japan and Amoor. Most of the garden varieties which have been introduced into this country and Europe are derived from *A. palmatum* of Thunberg. He gives as species *A. septemlobum* and *A. dissectum*, but these are only varieties of this species. Dr. Siebold called it *A. polymorphum* on account of its great tendency to vary in its foliage. It will thus be seen that these names which are given in nursery catalogues as distinct species, are only synonyms of *A. palmatum*. Strange to say, although the species was introduced into England as far back as 1820, none of the varieties were introduced until within the past few years. There is also a variety of *A. platanoides*, variously known in the European nurseries as *A. palmatum*, *A. crispum*, and *A. laciniatum*, which has the lobes of the leaves deeply jagged, with acuminate bristle-like teeth on the edges; this should not be confounded with the Japanese species. Dr. Savatier, speaking of the latter, says: "The form of the leaves varies much. Sometimes they are palmate with five to seven narrow lobes (*A. palmatum*, Thunb.) or divided into from seven to nine much larger lobes (*A. septemlobum*, Thunb.), or even more multiparted palmate, with narrow lacinations (*A. dissectum*, Thunb.). These three principal varieties subdivide themselves into many others, which the industry of Japanese gardeners has multiplied *ad infinitum*."

Thunberg gives the following description of this species: "Leaves palmate, serrate, smooth, flowers umbellate; tree medium-sized, entirely smooth; branches and branchlets opposite, round, turning purple, spreading leaves on the extremities of the branchlets, stalked, incisely palmate; 5-7 nerved, smooth on both sides; lobes 5-7 (Siebold says 3-9), lanceolate, acute, equally sharply serrate; nerves sometimes hairy."

Another class of the garden varieties is derived from *A. trifidum*. Their foliage is not so finely dissected and so Fern-like in appearance as that of the previous species. Dr. Savatier says, in speaking of it,

* Dr. Savatier and M. Franchet, in their catalogue of Japanese plants, enumerate twenty species, viz., *A. japonicum*, *A. Sieboldianum*, *A. pictum*, *A. truncatum*, *A. trifidum*, *A. diabolium*, *A. circumbolatum*, *A. Burgerianum*, *A. palmatum*, *A. capillipes*, *A. spicatum*, *A. tartaricum*, *A. miranthum*, *A. rufinerve*, *A. crægiiifolium*, *A. carpinifolium*, *A. distylum*, *A. argutum*, *A. pycnanthum*, *A. sessifolium*, *A. cissifolium*, and *A. nikonsense*. To these Dr. Maximowicz has added *A. tomentosum*, *A. monomaxim*, and *A. barbinerve*. Many of those enumerated by Dr. Savatier were discovered by Dr. Maximowicz.

Japanese Maple (*Acer palmatum dissectum atropurpureum*)

"The leaves of this species are very variable; are sometimes almost entire, sometimes more or less deeply trilobed; some have broad lobes, others have narrow ones, some are smooth on the edges, others are dentated." Thunberg describes it thus: "Leaves undivided, entire, trifid; branches round, smooth, purplish; leaves at the ends of the branchlets, few, undivided, bilobed, or trilobed, entire, on both sides smooth, above grass-green, below paler, ovate, acute; lobes ovate, acute, wide." Some of the varieties of this species have blotched leaves. It is very distinct from the previous species and produces correspondingly distinct varieties. It has larger, different shaped leaves and a stronger and different habit of growth.

A. japonicum is a very beautiful species, the leaves of which are large, almost circular in shape, and notched on the edge into eleven or thirteen sharp lobes. Multipartedly incised, opposite, serrate, on both sides downy, petioles short; the nerves at first hairy; branches and branchlets round, purple and smooth; umbels many flowered; flowers sub-umbellate, purple; seeds winged and woolly.

A. pictum has the leaves smooth, palmately seven-lobed; lobes acuminate, oblong, entire, alternate, aggregated together at the ends of the branches, smooth on both sides, variegated with white; branches smooth, ash-coloured.

A. carpinifolium is a rare species, the foliage of which is so unlike that of a Maple and so closely resembles that of the Hornbeam that none but the most experienced botanists would recognise it as a Maple, except they saw the flowers and the fruit. I am not aware of there being any varieties of it.

I do not think that *A. erataegifolium* has been introduced into this country, but a very beautiful variety with deeply incised leaves has been. It is of upright growth with brownish-red bark and is quite different in appearance from those derived from *A. palmatum*.

These are all that have been introduced into this country, as far as I know. The other species named would no doubt be desirable additions to our lists of ornamental trees. Many of them are closely allied to our American species, and can hardly be distinguished from them; for instance the Japanese *A. spicatum* differs from the American species of the same name, but not sufficiently so to warrant making it a distinct species. *A. circumlobatum*, *A. argutum*, and *A. barbinerve*, are allied to *A. glabrum*. *A. capillipes*, *A. rufinerve*, and *A. tegmentosum* are related to *A. pennsylvanicum*.

Much difficulty has been experienced in propagating the various varieties of Japanese Maples. As a rule they are of delicate growth and require to be grafted on some good stock to ensure a reasonable

strength of growth. They will take on some of the American species and will make a good growth for a year or two, when suddenly, sometimes within twenty-four hours, the whole plant will die. This could be overcome only by importing plants of the type to be used as stocks. The type can be propagated by cuttings, but as some of the trees originally imported are now beginning to produce seeds, stocks will be more readily obtained. The Japanese increase them all by grafting, but principally by inarching. As the varieties generally produce long, slender branches, they place a row of stocks—six, eight, or more—close to the mother plant, and 3 in. or 4 in. apart; they then inarch a branch at as many different points as there are stocks to graft it on, an eye or bud being left at each inarching. They propagate in this way in order to obtain as many grafts as possible, and not to dwarf the plants as is generally supposed. They also have a fashion of training up a stock with a clean stem 5 ft. or 6 ft. high, and then inarching a number of varieties—sometimes a dozen—upon it, on different sides, producing a very novel and beautiful effect. I trust that what I have just written will, in some measure, clear up the confusion which exists amongst horticulturists in regard to these Maples. Unfortunately nearly all the information that can be obtained about them can only be had in the works, difficult to be obtained, of Maximowicz, Savatier, Miguel, Siebold, and Bunge of the past few years, and of Thunberg and Trattinick of seventy or eighty years ago. No American or English botanist yet has made Japanese Maples a special study.—JAMES HOGG, in *Rural New Yorker*.

THE FLOWER GARDEN.

HARDY V. TENDER PLANTS.

WHEN I penned my few remarks on this subject (p. 504), I said nothing I thought that could hurt the susceptibilities of any thoughtful person, but might have offended the prejudices of some, and thus it appears I have done. A writer who might have replied in *THE GARDEN*, where my remarks appeared, but who has chosen to go elsewhere, devotes nearly a leading column ostensibly to Orchids, but really to my observations, and not being able to contest the question on its own merits, he expresses his dissent in personalities, weak ejaculations, and unsuitable rhyme. I am not therefore called upon to defend any particular assertion which I have made. If any one can demonstrate that the Orchids, &c., named by me are superior to the common flowers mentioned, in colour, form, singularity of blossom, or in any other way, let them do so. In my former remarks I only desired to direct attention to what cannot be regarded as anything else than a weakness on the part of cultivators generally, but, of course, exhibited in some individuals more than in others—what may, indeed, be called a kind of infirmity—an absence of discriminative perception—something akin to colour-blindness, for which the individual so afflicted is, I freely admit, not always responsible. There can be no doubt of the fact, however, that we are too apt to value the subjects which we cultivate by their cost and difficulty of culture, and gardeners lay themselves open to ridicule in this respect, and if there was such a thing as a horticultural *Punch* they would probably find it so. Employers are not so bad as their gardeners. A lady once said to me, "You know I cannot get up the enthusiasm for some of these things (pointing to some popular Orchids) that gardeners profess. They are no doubt pretty, and all that, but inferior to many of our common flowers that are quite neglected." And there is no use in disguising the fact that this is a very commonly entertained opinion amongst people of true tastes, and who are not bigoted admirers of this or that class of plants. Your contemporary compares the value of such subjects as the Calanthes with Snapdragons, Pentstemons, and Phloxes, as winter flowering subjects, which have nothing whatever to do with the question. The parallel is between plants for which extravagant admiration is professed, and those which have been well-nigh banished from our gardens because they were common, but which in real worth and beauty were every way superior. Where, for example, do we find any Orchids that surpass some of our hardy Lilies in grandeur, or our numerous Delphiniums in richness of colour or gorgeousness? Yet, when gardeners were wheeling these to the rubbish heap, a few years back, they were loud in their praises of Calanthes, indifferent Oncidiums, dingy Zygopetalums, and poor Epidendrums, &c., which could not be compared with them! I do not under-value good Orchids and other stove plants, but I cannot help often thinking of our inconsistencies in that way, hence my remarks.

In conclusion I would just state that the writer in your contemporary, in a style of exaggeration which is far too common and misleading, and quite inexcusable in one who should know better, states that the Calanthe Veitchi produces "gorgeous spikes of beautiful flowers in their varied shades of colour, from pale rose to crim-

son." This I wholly deny. The writer in question never in his life I am sure ever saw a crimson Calanthe Veitchi, and probably never will, nor anything approaching crimson—two, or maybe three shades of pink or rose, he may have seen, but hardly more, and the difference in these would be very slight. His description of the plant exceeds that given by any competent authority on Orchids, and is untrustworthy and quite inaccurate.

Since the above was written I see that Mr. Douglas has returned to the subject, hardy v. tender plants, in *THE GARDEN*, but nothing that he has there stated calls for any alteration in my remarks. One observation of his, however, requires comment. He says, "I must place a low estimate upon the tastes of the horticultural public" by my remarks. My reply to this is that there is not much faith to be put in the public taste in gardening any more than in other matters. What a commentary, for example, on the public taste was the banishment from our gardens of hardy flowers almost universally a few years back! After that I think vagaries such as I have alluded to need surprise no one. J. S. W.

— In a letter in another paper, I was interested to find Mr. Douglas philosophically deprecating any comparison between different classes of flowers—tender or hardy; presently, however, I was astonished to find him speaking of the "rubbish," and quoting poetry about some fair maiden who surpassed her fellows as much as Calanthe veratrifolia surpassed "nearly all the occupants of the herbaceous borders." Well, this is modest. The plant is very pretty, but, as a matter-of-fact (if it were needed in *THE GARDEN* above all other papers), I could give you a very long list of plants that surpass in beauty the one that Mr. Douglas mentions. Has he ever seen a tuft of the hardy Moccasin-flower (*Cypripedium spectabile*), nearly a yard high, grown on a north border in deep vegetable soil? Has he seen the magnificent Lilies that have embellished our gardens of late years, including *L. auratum*, 10 ft. high or more—columns of such splendid flowers as I have never seen on any exotic plants? Will he mention one so remarkable indoors? I quite agree with your correspondent that a good white Clove Pink is as good as a Gardenia; for me it is a good deal better. I do not desire to say anything against hothouse plants, but I should like to hear of anything in a hothouse so fine as a good double Stock in scent and colour too. Is there anything indoors among blue flowers that comes anything near the tall Delphiniums, grown, as I have seen them during the past year, to a height of 10 ft., and beautiful beyond all description as regards colour and form too? To the unprejudiced observer the beauty of a good collection of Irises growing on a favourable soil is more remarkable than that of any house of Orchids which I have yet seen. One of the fine varieties of the Cardinal-flower, with its splendid spike of scarlet, is unequalled in its way among tender flowers, as far as I know. The advantage of the indoor flowers being protected by the glass is a very great one, and I am afraid if they were exposed to all weathers like the Stocks and Clove Pinks, some of them would cut a very sorry figure. I have no wish to draw comparisons between different classes of plants, but I cannot allow anybody without protest to deprecate herbaceous plants who only appears to know those to which Calanthe veratrifolia is superior. I fear he must have looked at a very weedy, mixed border indeed. I much prefer to the Calanthe, which I also greatly admire, my group of the large Evening Primrose that scents my garden in the evening, and is so showy and beautiful throughout the night. I have also read somewhere in *THE GARDEN* that the Emperor of Austria has groups of this flower planted very near his country house, so that such a plant appears to be equally attractive to those who may have as many Calanthes as they desire. J. H.

RARE HARDY PLANTS.

Two plants have come under my notice since the past summer that have interested me much, and I seek for further and more practical information about each of them. The first is *Hugueninia tanacetifolia*, so named by Reichenbach after M. Huguenin, a celebrated French botanist at Chambéry; the other is *Nycteria Lychnidea*, a native of the Cape of Good Hope. The *Hugueninia* I noticed in some of the Italian valleys this autumn, south of the Hospice of St. Bernard, especially in one valley that leads down from the Mont Blanc range to Courmayeur and Aosta. It is a Crucifer, and it prefers valleys through which glacier streams appear to run. It grows in stony places among boulders that are Moss-grown. Its gay, bright-yellow colour, brighter than *Alyssum saxatile*, attracted my attention. It was growing overshadowed by Alders and glacier Willows, and the bright gold peeped out cheerily from the foliage. On examining the leaves of the plant, I remarked at once their resemblance in form to those of *Achillea macrophylla*, though they are more slender and graceful. It is a tall growing plant, of vigorous habit. I know nothing of its silicle but from books. I am wishful to learn if this has yet been in cultivation in England, and if so, with what result.

Now a few words on the other plant I wish to know more about from those who have treated it. I mean the *Nycteria Lychnidea*. It was once grouped with *Erinns*, but is wisely severed from that genus. As I said, it is a Cape plant. It was sent to me to name from a garden near Morecambe Bay. On first glance, without close structural examination, I felt inclined to group it with the *Lychnidea* or some allied group. Closer notice proved the fallacy of such grouping. Could it be a *Scrophulariad*? Happily a line from Mr. Baker, of Kew, who is always so ready to hold out a helping hand, settled the difficulty for me. This I know is in cultivation, but I know nothing about it. P. I.

THE WHITE-HOOPED PETTICOAT DAFFODIL.

(*NARCISSUS (MONOPHYLLUS) CLUSIL*.)

On December the 1st, when our thermometers registered 15° of frost, Mr. W. E. Gumbleton brought me from his garden at Belgrove, Queenstown, a very finely developed flower of this rare and beautiful little Daffodil, which, apart from its general interest, is remarkable as being perhaps the first one of the kind which has blossomed in Ireland. The late Mr. Giles Munby, of Alice Holt, Farnham, to whom we were indebted for the re-introduction of this little gem to our gardens, was ultimately tolerably successful as regards its cultivation after numerous failures and the trouble and expense of

The White-hooped Petticoat Daffodil.

importing batch after batch of its tiny brown bulbs from Algeria where it grows wild. The Rev. A. Rawson once showed me a specimen of it bearing fine flowers, and in Mr. Barr's nursery ground, at Tooting, a little bed protected by a frame produced twenty or thirty milk-white, golden-anthered cups all well-thrown up to the spring sunshine; but even with the knowledge and experience of its likes and dislikes gained by cultivators during the last five or six years, the plant is still rare in even good gardens, and the flowering of it is as yet always worth recording wheresoever it occurs. The behaviour of Mr. Gumbleton's plants, as he informs me, has been sufficiently singular. The bulbs were received in a vigorous growing state in the autumn of 1877. No growth at all was made during 1878, the bulbs lying dormant all the season, but in 1879 they grew freely enough and have just flowered. Mr. Gumbleton's flower as here sketched is the nearest approach to that figured in the "Botanical Magazine" which I have yet seen, and was far finer than native specimens which I obtained some years ago direct from Algeria by post through Mr. Munby. A lovely little plant like this is worthy of careful cultivation, since its flowers are ample reward, being unique in snowy-whiteness and delicate formation. F.W.B.

National Auricula Society's Schedule.—I noticed some remarks (p. 553) last week in reference to prizes being given for species of *Primula*, and I am pleased that it is thought to be a step in the

right direction. I hope there will be a good competition in this class as it is a most interesting one. I may also observe that prizes are likewise offered for fancy *Auriculas*, fancy *Polyanthuses*, and varieties of the common *Primrose*. This has been done in order that not a single member of the genus *Primula* may be left out. I see exception taken to the word "florist" as applied to these flowers. The term is certainly vague, as is also the term "fancy" as applied to the ordinary border varieties of *Polyanthus*, but such terms are used first in a haphazard way, then they gradually get into use, and it is difficult to get rid of them, even if better terms are suggested.—J. DOUGLAS.

THE KITCHEN GARDEN.

WINTER SPINACH.

At present, when choice vegetables are not over-plentiful, few things grown in the open air or in the kitchen garden are so much appreciated as Spinach. In places where four or five different kinds of vegetables have to be supplied daily, cultivators are often puzzled how to manage this, especially during severe weather or after frost, and to such Spinach must always be most welcome, as it may be gathered every day in the year, and it may also be used in a variety of ways in the kitchen. At the present time we have oftener a demand for Spinach than for anything else, and although we are annually increasing its cultivation, we see clearly that we shall require to increase it much more, on account of its being so useful in winter. Those who may not have been in the habit of eating Spinach, soon get to like it after having it served a time or two well cooked, and I must say that those who do not grow winter Spinach, or think they do not like it because they have never tasted it in proper condition, should try a patch of it next winter, when I am sure they will find it valuable in many ways.

We begin sowing our winter Spinach about the beginning of August, and sow now and then until the end of September. When winter sets in early, that sown early is the most useful; but during mild winters the latest sown patch often comes well in, and is most useful, especially, towards spring. Spinach will grow after any kind of crop, in stiff or free soil, and in rich or poor land. Too rich soil is not good for it in winter, as it causes the leaves to grow too large and tender, those of ordinary growth being the hardiest. We generally sow ours after Potatoes, and find it to answer well. The prickly kind, being the hardiest, is the only sort used for winter. The seed is sown in drills 18 in. apart and 1½ in. deep; the plants are not thinned until they are large enough for use, when all those drawn out are sent to the kitchen. Late-sown patches will just be about ready to draw now, and about this time Spinach should not be left too long in masses, as it is liable to rot.

In order to have ready access to it in all weathers, part of it should be covered over with frames and lights, or mats when frost or snow occurs; and Fern or straw may be spread over that which cannot be covered with frames. In mild weather it needs no protection.

CAMBERIAN.

Tom Thumb Savoy.—At the autumn show of the Ealing Horticultural Society, held the other day, Mr. Hudson, of Gunnersbury House, exhibited samples of the Tom Thumb Savoy that showed it to be a very desirable winter vegetable. Of all winter Cabbages, the Savoy is the hardiest, and therefore the safest to grow; but it acquires a strong taste as winter proceeds. The Tom Thumb kind not only does not exhibit this, but has also that smooth, delicate taste peculiar to the Brussels Sprout, and, being small, may be served up whole. It is especially a Cabbage for every-body's table, and, like the Rosette Colewort, should be planted thickly.—A. D.

Forcing Rhubarb.—The general scarcity of fruit this season will render forced Rhubarb doubly valuable during the earliest months of the year. Any one having good clumps may, by lifting them now with a large ball of earth attached to them, and planting them in any position where a little heat is available, even under stages where nothing else will grow, will have plenty of crisp, succulent stalks fit for tarts early in January and onwards. The largest market kinds are by no means the best for forcing. Moderate-sized stalks are the ones for quantity and quality.—J. GROOM, Linton.

Market Vegetables.—The best of all the winter green family for frosty weather is the Drumhead Savoy Cabbage. It is hardy, and maintains its firmness in frost better than others of the Cabbage tribe. When so hard frozen it is not possible to trim them neatly, and, of course, the heads are much more susceptible to breakage and injury; nevertheless when put into cold water for an hour or so before cooking, the frosted leaves are very tender and delicious eating.—D.

THE RIVIERA.

I AM pleased, as all must be, with Canon Hole's letters from Nice. They take me back so often to the sunny Riviera that I have known now for so many years, that I would fain add a few of my own experiences to those of your observant correspondent. I have made Nice, Cannes, Mentone, San Remo, Hières my winter homes for so long that I shall be excused if I seek to supplement, in some measure, and substantiate the remarks and observations of Canon Hole. I will begin with Nice itself. I was there in January, 1875. The flower market often attracted me. Here I saw fine sprays of *Buddlea madagascariensis* exposed for sale for a few pence, the creamy orange blossoms and leaves harmonising so happily together. This and *Cassia tomentosa*, if I mistake not, were great attractions to me; while among herbaceous plants were bunches of *Anemone stellata* in lovely flower. I would recommend Canon Hole to visit this market, if, indeed, he has not done so already. On the outskirts of the town, in the direction of the old Roman fort of Turbia—a grand walk—stands a giant tree of *Acacia lophantha*, with a girth the thickness of one's body; it was loaded with flowers and pods. That same walk gave me *Crocus versicolor* thus early, readily identified by Mr. Moggridge. I must not omit a somewhat local flower, *Moricandia arvensis*, which is essentially a Ligurian, occurring near to Ventimiglia as well as Nice. It is a Crucifer, and I may add very local in its distribution. Canon Hole would be interested, I doubt not, in seeing the fly that is so very detrimental in the grub state to the Olive crop; it is the *Tephritis Kairon*. M. Bruyat has bred it from the grub, and will be pleased to show it to any one interested in seeing this destructive fly. Again, M. Barla's collection of fungus-models at the museum at Nice is well worth a visit. They are life-like in moulding and in colouring, especially the Agaric group. I would draw especial attention to the models of *Coprinus picaceus* and *Ammanita cœsarea*. I think I can beat the Canon in his story of the spink. I once saw exposed for sale in a poulterer's in the Riviera, I think at San Remo, two dozen Jenny-wrens! These were part of the products of a chasseur's game-bag. I believe they were afterwards bought by an Englishman, who was a fly-fisher, for the sake of the feathers—at least I was told so. I shall be glad on some future occasion to supplement my account with notes from San Remo, Cannes, and other favoured spots of the beautiful Riviera.

Hovingham Lodge, York.

PETER INCHBALD.

Ivy on Buildings.—It is stated (p. 567) that Ivy keeps the walls of buildings dry, and that if they happen to be damp before, the damp will disappear after the wall is covered with the Ivy, which, it is also said, will suck out the moisture from the wall into its own substance, a statement in which there is a certain amount of both truth and error. Ivy will keep out damp from walls that were dry before, but it will not make walls that are already damp, dry, unless the damp is driven through from the outer surface of the wall only. The dampness of walls is not, however, often caused in this way; but rises from the foundations—sometimes as high as the second story, and when this happens the evil is very difficult to cure.

Much depends on the nature of the stone used and the situation, but all good architects now provide against damp rising by pitching the foundations at the ground line. The old parish church here is perhaps as perfect an example of an Ivy-clad structure as could be found, and the Ivy is kept in excellent order by careful trimming annually, yet the walls inside are so damp as to completely disfigure their surface, for which reason they have to be painted frequently. In this case the damp rises from the foundations. The Ivy has covered the walls for a very long period, and the latter appear to be drier outside than in, perhaps owing to the freer evaporation. I have seen many other instances of a similar kind. I do not know how Mr. Shirley Hibberd reconciles his opinion, that the Ivy sucks the moisture from the wall by its stem roots, as they are wrongly called, with the dictum of physiologists that the Ivy absorbs no moisture by these, not being a true parasite. If the plant derives any sensible nourishment in that way, how comes it that it dies so soon after the stem is severed at the bottom, the common way of killing Ivy on trees?—J. S. W.

Rose Stocks.—A mistake has occurred (p. 469) in reference to this subject. It is there printed—"and if their roots are strong enough to struggle with those of the other shrubs." I wrote, or meant to say, that if I recommend standard Roses to be planted amongst other shrubs, it is because the roots of the Dog Rose can struggle for life with those of other shrubs, the *Rosa canina* being one of our hardiest of plants.—JEAN SISLEY, *Lions*.

Late Black Hamburgh Grapes.—All I have to say in reply to Mr. Cowburn, who seems (p.) determined to prove that late Black Hamburghs are an impossibility, is that October-ripened Vines can be and are frequently kept from starting till May, and the fruit can be kept in good condition till January or February, for I have accomplished both, and seen the same done elsewhere. The Oak and the Ash never come into leaf here till about the middle of May, and are sometimes as late as the beginning of June, as they have been the last two years, and they are equally late in many other parts, and it would be strange indeed if Black Hamburgh Vines exposed to the cold, and with their roots outside, could not be retarded till the same period, seeing that they require a higher temperature than either the Oak or the Ash to bring them into leaf. I shall keep Mr. Cowburn's invitation in remembrance, and if he can show me ten Peaches, each within a fraction of half a pound, to the square foot I shall be the first to record the same.—J. S. W.

MESSRS. LETTS, SON & Co., of King William Street, City, have again issued their well-known diaries, and with them, Saxby's Weather Almanack, which was very successful in predicting the weather during the past year. The large amount of information which the author furnishes in this little work—which can be easily carried in the pocket—is based, not upon speculation, but upon scientific knowledge and painstaking observation, both night and day, of the many changes in the lunar system. He believes that not only has the moon an influence on our weather, but that it is likely to prove to be the main source of all atmospheric disturbances.

The Late Frost.—The thermometer fell to zero at Straffan Gardens, Co. Kildare, on the 17th inst.—F. BEDFORD.
